Ores:	Imports.	Exports.	Excess.
Tin ore, 1908...	7,445		Imp. 7,445
Tin ore, 1908...	9,421		Imp. 9,421
Pyrites, 1908...	275,084		Imp. 275,084
Pyrites, 1908...	301,777		Imp. 301,777

Copper totals include metallic contents of ore and matte. Exports include re-exports of foreign material. Of the imports in 1909 the United States furnished 128 tons copper matte, 788½ tons fine copper and 11,946 tons lead.

British Iron Trade—Exports and imports of iron and steel in Great Britain four months ended April 30 were valued as follows:

	Exports.	Imports.	Excess.
Iron and steel	£12,087,390	£ 2,503,331	Ex. £ 9,584,059
Machinery	9,180,589	1,544,038	Ex. 7,636,551
New ships	2,380,848		Ex. 2,380,848

Total.....	£23,648,757	£ 4,047,369	Ex. £19,601,388
Total, 1908...	26,392,140	4,311,580	Ex. 22,080,560

Total decrease in exports, £2,743,383, or 11.6 per cent.; decrease in imports, £264,211, or 6.1 per cent. The quantities of iron and steel were, in long tons:

	1908.	1909.	Change.
Exports.....	1,337,512	1,292,661	D. 44,851
Imports.....	342,136	374,935	I. 32,799

The increased tonnage of imports of iron was mainly in blooms, billets and other half-finished material.

Zinc and Lead Ore Markets

Joplin, Mo., May 22 Zinc sulphide ore sold as high as \$43 per ton, and the base price was advanced to \$41.50 for 60 per cent. zinc, with an unconfirmed rumor of a \$42 base. Offerings ranged down to a \$38 base for heads and some slimes sold as low as \$36@37 base. Zinc silicate ore

sold at \$14@24 per ton, the base offerings having about the same wide range, with a stronger demand for these ores the latter part of the week. The average price, all grades, was \$37.44. Lead ore sold as high as \$58 with small lots selling under \$57. The average price, all grades, was \$57.38 per ton.

Zinc prices began advancing Wednesday and the market continued feverish to the end of the week, when the offerings of \$41.50 base were made for delivery next week, with larger demand from several smelters.

SHIPMENTS, WEEK ENDED MAY 22.

On account of the condition of the mines, Highland, Linden and Harker are

not reported. In addition to the above there was shipped to the American Zinc Ore Separating Company 410,770 lb., and to the Joplin Separator Works 214,000 lb. zinc concentrates.

Chemicals

New York, May 26—A slight improvement begins to show itself in the market, rather more on contract than on current business.

Copper Sulphate—Sales are about the same and business is done at last week's prices—4.22½ per 100 lb. for carload lots, and 4.47½ per 100 lb. for smaller parcels.

Arsenic—Sales have been fair with quotations a trifle lower, at 2¼@2½c. per lb. for white arsenic.

Nitrate of Soda—The market for this article continues good and prices have advanced a little, 2.25c. being asked for spot nitrate and 2.15c. for future positions.

Potassium Salts—Exports of potassium salts from Germany for the quarter ended March 31 were, in metric tons:

	1908.	1909.	Change.
Kainit, kieserit, etc.	147,129	173,998	1. 26,869
Potassium chloride.....	27,744	41,841	1. 14,097
Potassium sulphate.....	9,560	13,895	1. 4,335
Pot.-magnesium sul.....	38,557	30,580	D. 7,977
Total.....	222,990	260,304	1. 37,314

Of the exports this year in all \$4,080 tons went to the United States.

Fertilizers—It is reported that the combination of independent fertilizer manufacturers may fail, J. P. Morgan & Co. having withdrawn the financial support expected from them.

Mining Stocks

New York, May 26—The general stock market has been less active than for some time and inclined to be irregular. It has been a traders' market, with comparatively little outside influence and few disturbing factors. Consequently, it has moved up and down in a rather irregular way and has shown no very definite tendency. At best there has been rather a cessation in the bull movement, but without any general break. The most marked feature has been the great strength of Steel Corporation stocks, which have continued to rise, the common stock advancing to record quotations. It is to be noted that J. P. Morgan, Jr., has been chosen a director of the Steel Corporation to succeed H. H. Rogers—not a Standard Oil man, as was expected.

There was one sale during the week of Homestake, of South Dakota, 100 shares changing hands at \$92 per share.

On the Curb the copper stocks have shown small fluctuations, but no important changes. The movement was divided, some stocks losing a little, while others gained. Sales were only moderate. The Nevada gold stocks are improving in

price and demand, while Cobalt stocks did a moderate business.

Boston, May 25 North Butte has again been the market feature; continued liquidation and bear manipulation have resulted in putting a quietus on the general mining share market. It broke from \$62 to \$55.50, recovered to above \$59, and fell back again to under \$57. The public is in the dark as to the actual condition of the company, but the best belief is that the property has fallen behind. The declaration of a \$6 dividend by Calumet & Hecla lends encouragement to the situation, as it is a small increase over recent payments. Calumet dividends have always been in multiples of \$5, so that this rate is an unusual one.

Amalgamated has fluctuated between \$82 and \$84.50, but closes about the same as a week ago. There is no pressure to sell mining stocks and the odds are that prices will work higher. United States Smelting has had a \$3 advance to \$50.50, while the preferred is also up to \$47.50 to \$50. There is pool work in this stock and these movements are facilitated by reason of the fact that all discords in the management are ended. United States Coal and Oil, the management being the same as United States Mining, has advanced from \$31.50 to \$34. Butte Coalition and Parrot have been strong spots.

Prices on the Curb have been firm for the higher-priced issues. Yukon has risen \$1 to \$5.25. Helvetia had a good advance also.

Industrials

W. L. Imlay Rapid Cyanide Process Company, Philadelphia, Penn., reports having closed its first 100-ton daily plant with the Gold Ridge Mining Company of Alabama.

The Wood Drill Works, of Paterson, N. J., has a number of copies of an enlarged sectional cut of the "Wood" rock drill which they are distributing gratuitously among mining schools desirous of securing a copy.

Buckeye Engine Company, Salem, Ohio, announces the appointment of Louis Bendit, as Kansas City sales manager, with offices at 504 N. Y. Life building, and J. R. Detweiler, as district manager, 505 Barnes building, Wichita, Kan.

Among the recent orders received by Tate, Jones & Co., Inc., Pittsburg, Penn., is an extensive one from the Erie Forge Company, Erie, Penn., for fuel-oil burning equipment for use in open-hearth furnaces. Uniformly, low cost and a steady supply are given as the reasons for the installation of oil over other fuels.

The Wagner Electric Manufacturing Company has opened an office in Denver, Colo., located in the Ideal building. This new office is in charge of O. H. Davidson, of the Electric Manufacturers' Sales Company. Mr. Davidson will have charge of the Wagner Company's business in Colorado, New Mexico, Utah, Montana and eastern Idaho.

The Independent Pneumatic Tool Company, of Chicago, Ill., has recently appointed the Burnite Machinery Company, 1710 Glenmar street, Denver, Colo., exclusive Colorado agents for their well known line of Thor pneumatic tools. A full line will be carried in stock, including piston air drills (reversible and non-reversible); pneumatic reaming, tapping and flue rolling machines; pneumatic wood-boring machines, pneumatic riveting, chipping, calking and bending hammers; pneumatic grinding machines, saws and flue expanders, repair parts for all machines. All orders for Colorado and vicinity should be sent to the Denver office.

John L. Wagner, vice-president of the Pneum-electric Machine Company, Syracuse, N. Y., spoke before the mining engineers' department of the State College of Pennsylvania on Wednesday, March 24, on "Mining Coal with the Electric Puncher." His paper, which was illustrated by numerous lantern slides, presented briefly the history of the application of electricity to coal-mining machines and showed in detail the latest designs of the Pneum-electric coal puncher, which represents the only machine of the reciprocating percussive type directly operated by a motor forming a part of the machine, and the only type in which the air is both compressed and utilized within the same cylinder.

S. B. Stine reports having recently closed contracts for the following complete ventilating equipment: The Maderia Hill Coal Mining Company, one 10-ft. fan, with engine; Cabin Creek Consolidated Coal Company, Kayford, W. Va., one 4-ft. direct connected fan, with Westinghouse motor; one 8-ft. belted fan and one 6-ft. belted fan; the Turkey Gap Coal Company, Ennis, W. Va., one 6-ft. fan and engine; the Price Coal Company, Ethel, W. Va., one 7-ft. fan and engine; the Rex Coal Company, Ethel, W. Va., one 8-ft. fan; Leachey Coal Mining Company, Lilly, Penn., one 5-ft. fan and engine; the Lambert Run Coal Mining Company, Fairmont, W. Va., one 5-ft. fan and engine; the La Belle Coal Company, Wellsburg, W. Va., one 5-ft. fan. J. T. Beard, the Scranton expert, has taken charge of the fan department of S. B. Stine and will act as his consulting engineer.

The Jeffrey "Lock-Jaw" wrench is the simple practical, common-sense development of the demand for a wrench whose jaws would not spread. Every man familiar with the severe

service of track work realizes clearly enough the constant drain of expense in taking care of this troublesome complaint. The expense of wrench repairs has grown up through the years close and tight to the great body of maintenance costs. It requires, therefore, the closest investigation from a new standpoint—with the aid of the Jeffrey "Lock-Jaw" as a prod and wedge—to show up clearly how this clinging growth can be wrenched loose. Once rid of such expense, the Jeffrey "Lock-Jaw" wrench will be constantly in service as a safeguard against all future expense for track wrench repairs. Any wrench which fails through spreading of its jaws will be replaced free of charge.

The Curtis rotary pump is a positive rotary pump, that is to say, it can be used on high heads as well as low heads. This pump was designed more especially for mine service, although it is adapted for any service where piston pumps can be used. They are usually made iron bronze-lined, but for acid-mine water are constructed of solid acid resisting bronze. The blades or buckets in revolving rotor are made of wood or an anti-friction composition. The bearings in the heads are made exceptionally long and are either high-grade babbit or lignum vitae and are supplied with exceptionally large grease cups where grease can be forced down by application of wrench with heavy plungers. The pumps are made in all sizes from 50 g.p.m. to 2000 g.p.m. capacity. The machine work on them is especially high grade. They are peculiarly adapted for mine service and take up very little room and are easily handled. The pumps are manufactured by the Pittsburg Machine Tool Company, N. S., Pittsburg, Penn.

Wm. Ainsworth & Sons, Denver, Colo., have just placed on the market a new theodolite for mountain and mining work. By the use of the hardest bronze alloys the weight of this instrument has been reduced to a minimum without sacrificing rigidity, and the U or theodolite standard, the merits of which are now well recognized, is so designed as to admit of placing a 24-in. compass in the center, which is sufficient for checking. It has 44-in. limb and vertical circle with edge graduation, 8-in. 20-power main telescope, 7-in. 18-power auxiliary telescope with counterweight that may be used either as a top or side telescope, 4-in. 30-sec. telescope level, stadia, gradienter, magnetic variation circle, 4-screw leveling head and extension tripod. The instrument weighs only 9 lb., complete with all attachments. The limb verniers are placed at 30 deg. with the line of sight, which together with the edge graduation on the vertical circle, enables an operator to read both vertical and horizontal angles from the one position. The telescope tubes are finished in an improved manner, insuring perfect collimation for all distances. Only the highest grade lenses ground according to the latest formulas are used. The telescope axis has the usual grooved bearings common to all this firm's instruments, the merits of which are now well recognized. The leveling head is of improved design and accurately constructed so that it cannot be cramped in any position, which greatly reduces the wear on the leveling screws and renders it unnecessary to loosen all of the screws when leveling up. The shifting center has a movement of $\frac{1}{2}$ in. to permit locating plumb bob over point. The graduations, with the exception of the compass circle, are on solid silver and produced on their new 30-in. automatic dividing engine, which machine it is claimed is capable of producing automatically circles accurate to within one second of arc. The instrument is fully described in their catalog "BX."

The Bunker Hill screen, introduced by the Hendrie & Holthoff Manufacturing Company, Denver, Colo., consists of an inverted truncated cone formed by stretching the screen cloth over a suitable wrought iron frame. This cone is

attached to a hollow shaft set at an angle of 45 deg. and driven by bevel gearing and tight and loose belt pulleys. The hopper, also cone shaped, is fastened to the frame. It has near its bottom a discharge opening for the undersize, and carries a bracket which supports the feed box. The feed box is of sheet iron and contains a regulating shutter valve. The whole screen is mounted on a cast iron frame and is entirely self-contained. The screen is supplied with two spray pipes; one on the inside, adjustable by means of a universal joint and located on the side opposite to the feed box, and the other outside passing down nearly vertically between the screen and the hopper. The feed is deposited on the screen a little below the meridian line and falls in the same direction as the travel of the screen. The ore current may be thickened or thinned as occasions may require, by means of the shutter valve above referred to. The oversize is discharged through the hollow shaft and the undersize through the pipe tapped into the hopper surrounding the screen. The inner spray pipe washes through the screen any small particles that may not have passed through its meshes, while the outer spray pipe serves to keep the meshes open and prevents blinding. From the foregoing description it is readily seen that, on account of the conical shape of the screen, its peripheral speed is constantly varying in direct proportion to its different diameters at different sections. For this reason and also on account of the slight centrifugal force to which the particles to be screened are subject, they are forced to undergo a twisting motion, presenting all different faces to the wash water and the screening surface. The capacity of the Bunker Hill screen ranges from 25 to 50 tons per day and even more on certain ores. This is rather surprising, but not to those who have had occasion to know the screen from its inception, and have familiarized themselves with its working. Since the oversize is speedily washed away and discharged as soon as formed it does not occupy useful screening surface and block the way of the small grains. It is almost necessary to see the screen at work before one can realize its extraordinary capacity.

An Ore-transporting Railway in the Pyrenees

The Line Is Divided into Three Sections, Consisting of a Loading and Terminal Wire Rope Tramway, Connected by a Local Railway

BY A. GRADENWITZ*

In the most beautiful part of the eastern Pyrenees, at the famous winter resort of Amélie-les-Bains, terminates one of the most interesting wire-rope railways ever constructed for the opening up of inaccessible mining districts. Though the level differences and other difficulties to be dealt with were not such

Valentine Brothers, of Paris, are the owners of an extensive iron deposit below Mount Canigou, a peak 2800 m. in high, covered with everlasting snow. The average iron content of the ores is 50 per cent. The ore is taken either to Port Vendre on the Mediterranean, in order to be loaded on ships and

through which the ore is dumped toward the lowermost gallery; there it is loaded into trucks and taken to the bunker of the wire-rope railway (Fig. 1). The mines are at present being equipped with electrical drills and locomotives. The whole of the transporting plant, from the La Pinouse mines, situated at 1350 m. high,

FIG. 1. SURFACE PLANT AT THE MINE SHOWING LOADING STATION OF THE AERIAL TRAMWAY

as in connection with the well-known Cordilleras railway (35 km. in length and rising to 4500 m. in high) still its design, characterized by enormous spans traversing the most savage and cloven mountain landscapes, renders this plant of unusual interest.

conveyed to English metallurgical works, or transported direct by rail to the Schneider works of Creusot.

MINING AND LOADING THE ORE

The process of working the ore is fairly simple: Galleries driven at different heights are connected by vertical shafts

down to Amélie, was divided into three sections corresponding to the special nature of the mountains, viz., two wire-rope railways and a local railway connecting the two. While not great, the level difference negotiated by the upper wire-rope railway, 1.3 km. in length, is sufficient for the railway to work independ-

*Berlin W. 50, Regensburgerstrasse 3.

cally, with a surplus of 10 h.p. which is used up by hand-regulated bands. The wire-rope trucks are loaded from a bunker erected on the mountain slope and are despatched at regular intervals.

The most interesting part of the upper wire-rope railway is the huge span (Fig. 2) traversing a deep valley 450 m. in width, immediately before the discharge-

locomotives, carrying in each train 50 tons of ore. Having a level difference of only 200 m. the railway is situated throughout its length on mountain summits, the steep descent down to Amélie only beginning behind La Redoute. The station forms the center of operation for the local and wire-rope railways and with its extensive plants, repair shops and

is here nearly 900 m. and with a load of nearly 50 tons a surplus of nearly 100 h.p. is developed. On account of the enormous level difference, the railway has been subdivided into two sections of equal length with an intermediary station at the village of Can Kirk. At that intermediary station, as well as at La Redoute, are installed hydraulic braking regulators, de-

FIG. 4. UNLOADING STATION AT RAPALOUN

FIG. 5. ORE BINS ABOVE LA REDOUTE LOADING STATION

FIG. 6. UNLOADING BINS AT RAILROAD STATION AT AMÉLIE-LES-BAINS

ing station. Down in the valley are situated the water-power plants built by the mining company for supplying the mines with power and light.

THE RAILROAD SECTION

The station of Rapaloun (Fig. 4) is erected on a steep rocky wall towering from the valley where the transfer is effected into the cars of the local railway. The ore is then transported in trains by tender locomotives to the station of La Redoute, 14 m. distant (Figs. 5 and 8). The entire tonnage is handled by three

dwelling for machinists, guards and locksmiths, resembles a small village.

TRANSFER TO THE TERMINAL SECTION

The transfer of the ore is effected in the usual manner by means of a bunker in front of the ore bunker extension; within the substantial lining wall, the wire-rope trucks are shoved along and filled, after which they are coupled in the station to the rope for transfer to the terminal section, 4½ km. in length leading down to Amélie. The difference in level

signed as vane pumps, driving water through a narrow slot. The resistance varies according to the number of descending trucks, which obviously cannot be kept constant, as well as to atmospheric conditions, so that the braking effort must be altered by narrowing or widening the slot so as to keep the speed constant. This is effected by a centrifugal regulator connected to the traction rope, which with any alteration in speed, adjusts the width of the slot.

The railway on its way to Amélie-les-Bains traverses several wide valleys

Fig. 3 represents one of the lofty supports which on either side of these valleys form the last abutment of the rope. At the station of Can Kirk, the trucks are loosened from the rope and, owing to their live force, they go on over the slightly sloping suspended rail, deviating laterally, and are again coupled, at the station, to the track rope of the lowermost section. The railway gradually descends, penetrating into the vineyard district of Amélie (Fig. 7) and, terminating at the railway station of Amélie-les-Bains, where another large bunker for receiving the ore has been erected (Fig. 6). By means of folding chutes, the ore is drawn off into the cars of the Southern Railway Company and taken to its final destination.

CONSTRUCTION

As regards the construction of the railway, it may be said that the whole of the runway consists of closed ropes offering

Prospecting for Ores of the Goldfield Type

By J. VOLNEY LEWIS*

"In the Goldfield district alunite is so abundant and so generally associated with the intense alteration accompanying ore deposition that it must be looked upon as one of the most characteristic minerals of the gold deposits."¹ With this announcement Ransome not only added a new type to the geology of ore deposits, but pointed out a most promising new field for exploitation. The prospector, however, has not rushed in to possess the new land. He has rather roamed about blindly over vast areas of desert and mountain in the hope that somewhere, somehow, he would stumble upon the coveted treasure; but no practical means has been put into his hand for recognizing the ore he seeks.

There is gratifying evidence that the

on very different looking ledges, and only a tenderfoot would pause for a second look at the unstained outcrop. To the prospector in the desert all this has now been changed. If he has learned the lesson of Goldfield he knows that amazing values have been developed there in a beautifully white porcelain-like material for all the world like the most barren porphyry; and now others are duplicating this Goldfield experience in far-away corners of the desert, while vast inviting fields still lie unexplored.

I do not mean to say, of course, that iron-stained material is not found at Goldfield, both on the outcrops and in the mines, but merely that this is not a necessary or characteristic feature of deposits that carry high values.

Under such conditions what is the prospector to do? He cannot sink pits on every ledge, whether rusty or white, and have assays made all over the face of the earth. Besides, the assayer may miss the

FIG. 7. TOWER ON LOWER TRAMWAY NEAR AMELIE-LES-BAINS

FIG. 8. LA REDOUTE STATION, SHOWING BEGINNING OF LOWER TRAMWAY

a smooth surface to the rollers so as to be subject to less wear and tear and to put the rollers to less strain than would a spiral rope consisting of round wires. A clutch of standard Bleichert design is used for connecting the trucks with the traction rope. This clutch, which in the present case acts on the lower rope, is constructed in one with the driving gear, insuring the vertical suspension of the car independently of any inclination of the supporting rope. A special advantage of this design is that ropes of fairly different diameters are seized with the same security which in this special case is especially welcome, as the traction ropes on the two sections of the lower wire-rope railway are never stretched with absolute uniformity and accordingly are bound in the long run to assume different dimensions. The traveling speed on the upper wire-rope railway is 2 m. and on the lower 2.5 m. per second. The plant was constructed by Adolf Bleichert & Co.

scientific prospector, the mining geologist,² is availing himself of the new knowledge to more purpose; but the vast area that may possibly bear this type of ore is too much for the few scientific men who are in the field. If the present generation or the next is to realize in any large degree the possibilities that have been opened up, we must enlist the larger army of practical mining men.

THE PROSPECTOR'S DILEMMA

The prospector who knows his porphyry, his limestone, and the honeycombed rusty gossan that bespeaks the deeper-lying sulphurets has been taught by long experience to disregard all manner of whitish or grayish or clean-looking rock. The big mines that he knows have been opened

main point altogether. There may not be enough gold in the cropping or in the shallow pit to excite the mildest interest, but if alunite is there the prospector wants to know it, whatever the values, for it is worth while to follow it down a bit and try the assayer again on the deeper levels. Of course, alunite does not everywhere and under all conditions indicate the presence of gold; neither does rusty quartz nor any of the various "indications" by which the prospector is guided; but the abundance of the mineral and the constancy of its association with the ores at Goldfield, followed now by a similar occurrence in a new locality, are extremely suggestive; and there are large areas in the Southwest where geological conditions are closely similar.

MINERAL CHARACTERS AND OCCURRENCE OF ALUNITE

Alunite occurs in hard, white, porcelain-like masses, or in fine-grained condition like loaf sugar. In the latter case it is

*Mining geologist, Washington & Lewis, Singer building, New York.

¹ F. L. Ransome, "The Association of Alunite with Gold in the Goldfield District, Nevada," *Economic Geology*, Vol. 11, 1907, p. 609.

² Dr. T. H. H. Engineering and Mining Journal, Dec. 5 and Dec. 12, 1908.

either firm like marble, or it may be easily crumbled into a snow-white mass resembling pure kaolin and difficult to distinguish from it in the mines. At Goldfield it often has a pale pinkish color, while the kaolin is white. Sometimes it is found in little square-looking crystals (rhombedrons) which form nests in the small openings of the rock, but these are rare and have never been seen as large as $\frac{1}{4}$ in. in diameter. The mineral is easily scratched with a knife ($H. = 3.5 - 4$), which would serve to distinguish it from similar masses of quartz and feldspar ($H. = 6$ and 7 , respectively); but feldspar that is changing to kaolin would be soft also, and alunite is often so intermingled with both quartz and feldspar that its true characters are entirely masked. The fact that a substance does not readily yield to the point of the knife, therefore, is no proof that alunite is absent. The character of alunite and its frequent association with sulphides also prevents the use of any simple blowpipe test for its recognition.

Alunite has been found with gold in a number of closely related types of volcanic rocks (rhyolite, latite, andesite, etc.), all of which are generally gray or greenish or some lighter color, unless stained by iron from decomposing sulphides, and are generally known to the miner and prospector as "porphyry." It does not occur in these rocks in their unchanged natural condition, but has been formed along planes of fracture and crushing produced by faulting. But the rock that was crushed by the grinding of moving masses upon one another has been in many cases firmly cemented together again by the quartz that has been deposited through it. Hence it may be as hard as any of the country rock; but its color is usually changed in the process, and it is often much whiter, except where stained by iron from rusting sulphides. Pyrite often accompanies the alunite in these altered rocks, and gypsum is frequently found in very soft, white films along the cracks and seams.

USE OF THE MICROSCOPE

If a rock specialist from some college or university should turn prospector he might utilize his knowledge that a thin section of the rock under the petrographic microscope usually affords an easy method of recognizing the elusive alunite; but, like the prospector who must have everything assayed, he would work at a great disadvantage because his method cannot be carried into the field. He must grope in the dark, collecting materials from faulted and altered rocks for innumerable thin sections, and must await their preparation and examination before he knows whether he has found a promising locality or not. Besides, even the petrographer must sometimes halt between two opinions when the microscope fails to distinguish alunite from extremely minute particles of quartz

and feldspar. In such cases the chemist must be called in to make the final decision.

THE APPEAL TO CHEMISTRY

The chemist, then, is the man to whom we naturally turn for the practical key to the situation. A short, reliable chemical method is what the prospector most needs, requiring only materials that can be carried into the desert with him without hampering his movements or restricting his grub supply. It is just this need that Mr. Gage has undertaken to meet in the second part of the accompanying paper.

In the microscopic study of alunite-bearing rocks I have often found that the results required chemical confirmation. Fortunately, Mr. Gage, who did this work for me, brought to the task not only a full understanding of the difficulties to be overcome, but also the ability to devise effective methods. In the absence of established methods for analyzing such complex mixtures of sulphates, sulphides and silicates, he has worked out the procedure which he describes in the first part of the accompanying paper, and the results have been highly satisfactory. With a view to making the method immediately available to the prospector or engineer in the field, he has further devised a qualitative modification which should not prove difficult for the nontechnical man. It is earnestly hoped that it may serve the prospector's purpose in searching for the Goldfield type of ores, which until now he has had no means whatever of recognizing.

Determination of Alunite

By R. B. GAGE*

The importance which the mineral alunite has attained in the last year and a half on account of its association with and relation to the gold ores of Goldfield, Nevada, makes a method for its determination very desirable, not alone for its quantitative estimation in the laboratory, but one that can be applied in the field qualitatively in order that the presence or absence of alunite may be determined at once. This would be a comparatively easy matter if the mineral did not occur associated with other sulphates and often also with sulphides.

Alunite is a basic sulphate of potassium and aluminum whose composition may be expressed by the formula,

Sodium may replace a portion of the potassium. Since the deposits of this mineral with gold seem to have been formed by the action of sulphuric vapors on feldspars, more or less gypsum is naturally to be expected if the original

rock contains any of the lime-bearing, or plagioclase feldspars. Microscopic examination, by J. Volney Lewis, shows that both orthoclase and plagioclase feldspars are always present, and in nearly all specimens of the altered rock examined by me more or less gypsum has been found. Sometimes it is present in much smaller amounts than alunite, but often just the reverse is true.

Although alunite is affected but little by either strong or dilute hydrochloric acid, it is slowly soluble in strong sulphuric acid and is also readily decomposed by hydrofluoric acid. When the mineral is heated alone to a dull red it is decomposed with the formation of alum and the loss of water and more or less sulphur trioxide. At a higher temperature the latter is given off freely.

QUANTITATIVE DETERMINATION

1. *In the Absence of Sulphides*.—For the quantitative estimation of alunite an indirect method must be employed in order to separate it from the other sulphates. When no sulphides are present a total sulphur determination is made as follows: One gram of the powdered material is mixed with five grams of sodium carbonate, to which is added a small crystal of potassium nitrate, in a platinum crucible of 30 c.c. capacity. The crucible should be heated first over a Bunsen burner and then over the blast until the material is completely decomposed. When the fusion no longer continues to give off bubbles of gas this point has been reached. The crucible should rest in an opening cut to fit accurately in a piece of asbestos cardboard in order to guard against the absorption of sulphur from the gas. The flame from the blast should heat that part of the crucible beneath the asbestos board to a uniform temperature; that is, a broad flame should be used rather than a pointed one.

The melt is digested in about 200 c.c. of hot water until completely dissolved, and then filtered. The filtrate contains all the SO_3 in the sample, together with more or less silica and alumina. The volume of the filtrate should not be less than 250 c.c., and it must be neutralized very carefully (with strong hydrochloric acid) or silica will separate out. If the acid is added slowly while the solution is stirred silica is sure to precipitate. When this happens the silica will have to be dehydrated by evaporating to dryness or another fusion must be made, as it is impossible to filter the gelatinous silica. A blank should be run, using the same weight of chemicals and the exact amount of strong hydrochloric acid added that will be required to decompose the carbonate used. The end point can be easily determined by adding a drop of methyl orange, which is not affected by the CO_2 given off.

To the filtrate from the fusion of the mineral the required amount of acid and

*Chemist, Geological Survey of New Jersey, Trenton, N. J.

about 1 c.c. in excess is added by allowing it to flow slowly down the side of the covered beaker. The solution should be set to one side until the acid has worked its way nearly to the bottom of the liquid, which it will soon do as the escaping gas keeps the liquid in motion. When the carbonates have nearly all been decomposed the solution should be stirred up vigorously for a moment and then heated to boiling. It should remain perfectly clear. If a slight precipitate appears, it should be filtered off. In either case 25 c.c. of hot barium chloride solution are added to the boiling solution and the mixture kept near the boiling point until the precipitate has settled, leaving the solution quite clear. Since the precipitate has a tendency to pass through an ordinary filter paper, a very thick one should be used. The clear liquid is gently decanted through the filter without disturbing the precipitate any more than necessary. After discarding the filtrate the precipitate is transferred to the filter and washed free from chlorides with hot water. The paper and precipitate are then transferred at once to a weighed platinum crucible and gently ignited over a Bunsen burner, cooled and weighed.

If there is any reason to suspect that the precipitate of barium sulphate is contaminated with silica or has been reduced on ignition of the filter paper, it should be moistened with water containing a few drops of hydrofluoric acid and a drop of sulphuric acid added. After evaporating to dryness a few drops of ammonia should be added and then expelled by heating. A second treatment with ammonia may be necessary in order to remove the last trace of sulphuric acid added. The crucible should be heated to a dull red after each treatment. It is finally heated to a bright red over a Bunsen burner, cooled and weighed. From the total SO_3 thus secured deduct the amount found to be present in sulphates other than alunite. The remainder thus determined, when multiplied by 2.5906, will give the alunite content of the sample.

The Separation of Gypsum.—The method for the separation of alunite from gypsum is based on the insolubility of the former and the solubility of the latter in distilled water. Since it requires about 425 c.c. of water at 90 deg. C. to dissolve one gram of gypsum, the volume of the solution should never be less than 300 c.c. This amount will usually insure a large excess of the solvent, since the sample will seldom contain as much as 50 per cent. of gypsum. It is always advisable, as a check, to determine both the CaO and the SO_3 in the solution of gypsum, for often the sample will contain small amounts of soluble sulphates other than gypsum.

A test was made on a sample of nearly pure alunite and 0.34 per cent. of SO_3 was found to be soluble in hot water, although no CaO nor Al_2O_3 was dissolved. It

is possible that this SO_3 may have come, in part at least, from the alunite, but since the specimen was not entirely pure and the amount of SO_3 taken into solution was less than one-hundredth of 1 per cent. of that present in the mineral, it is assumed in the method of procedure here described that the alunite is entirely insoluble in water. Therefore, any excess of SO_3 in the water solution over what is required by the lime to form gypsum may be assumed to come from soluble sulphates other than gypsum and is to be deducted, along with that in the gypsum, from the total SO_3 in the rock in order to determine the amount present in alunite. Sometimes the CaO in the water solution is in excess of the amount required to combine with the SO_3 to form gypsum. In this case it is impossible to tell whether or not any other soluble sulphates are present.

The actual operation is carried out as follows: One gram of finely powdered material is digested with 300 c.c. of distilled water for about one hour. The aqueous extract is filtered through a very thick filter paper (or two papers), as some of the undissolved sample will usually pass through an ordinary paper. The filtrate is made slightly ammoniacal and heated for some time. Should a slight precipitate appear it is filtered off. In either case the CaO is precipitated in the hot filtrate as the oxalate. The solution should be kept near the boiling point for at least 30 min. before filtering. A re-solution and reprecipitation of the lime is not necessary, since little or no magnesia is present.

A prolonged washing of the precipitate should be avoided, since calcium oxalate is not totally insoluble in hot water. Paper and precipitate are transferred without drying to a platinum crucible and the paper slowly incinerated. After the precipitate has been heated over the blast lamp for a few minutes it should be cooled and then moistened with a few drops of water and the same slowly evaporated off, when it is again heated until it no longer loses weight. It should always be cooled in a desiccator and the weighing done as rapidly as possible, as it absorbs moisture quite rapidly from the air.

The filtrate is then made slightly acid with HCl and the SO_3 determined in the manner described above. The presence of oxalic acid will doubtless cause a slight error by keeping a small amount of barium sulphate in solution, but it is probably no greater than that which would be caused by the contamination of barium sulphate with calcium salts if the SO_3 was determined without first removing the lime.

From the amount of CaO and SO_3 found the gypsum content is calculated. The SO_3 of the gypsum, plus that of other soluble sulphates present, is deducted from the total amount of SO_3 found in the rock in order to determine the SO_3

contained in the alunite. Should the material contain other insoluble sulphates than alunite, which is possible but not very probable, the results thus secured will be correspondingly high.

Owing to the nature of alunite and the substances that are usually associated with it, the results obtained by the methods described above do not possess the high degree of accuracy attained in the better analyses of ordinary rocks. In most cases, however, the errors will be so small that they may be neglected.

II. When Sulphides are Present.—When pyrite is present the total SO_3 cannot be determined by the method given above. In this case a gram of the powdered material is transferred to a 300-c.c. platinum dish and decomposed with hydrofluoric acid. The residue after evaporation is moistened with strong hydrochloric acid and again evaporated to dryness, in order to expel as much of the hydrofluoric acid as possible. After moistening the residue again with a few drops of hydrochloric acid, it is digested with about 250 c.c. of hot water until all the soluble salts have gone into solution. It is then filtered and well washed with hot water. The SO_3 is determined in the filtrate in the manner described above.

Pyrite is attacked but slightly, if at all, by hydrofluoric acid. The solution should contain a little free hydrochloric acid in order to prevent the precipitation of barium fluoride with the sulphate, but too much acid will also prevent the complete precipitation of the barium sulphate. The hydrochloric acid used to moisten the residue may be sufficient if the final volume of the filtrate is not much over 300 c.c. If the precipitate is thought to be contaminated with barium fluoride, which is generally the case, the supernatant liquid is gently decanted, 2 c.c. of strong hydrochloric acid added, and the contents of the beaker gently warmed for a few minutes, when it is again diluted to about 300 c.c. and allowed to stand the usual length of time before filtering. Barium fluoride is a white flaky precipitate that will not settle to the bottom of the beaker like barium sulphate, hence anyone familiar with the appearance of the latter will have little difficulty in distinguishing it from the former, unless the amount of the barium fluoride precipitated is quite small compared to that of the barium sulphate. In this case it is impossible to distinguish them.

QUALITATIVE DETERMINATION IN THE FIELD

A chemical test for the presence of alunite is a very simple matter and can easily be made in the field where water that is free from sulphates can be obtained. The necessary apparatus includes two or three pint tin cups (or tin cans may be used), a small mortar, and a spoon, cartridge, or other measure that will hold about a gram (15 grains) of the

powdered rock. (A 0.44 caliber cartridge one inch long will hold about half a gram of powdered rock.) A few ounces of barium chloride will also be needed.

When a test is to be made for the presence of alunite a small piece of the rock is first pounded up with a hammer and then ground to a fine powder in the mortar. About a gram of the powder is measured out into a tin cup which is nearly filled with water. The water is then boiled for 15 or 20 min. and allowed to stand until all the powder has settled. The clear water, which contains in solution whatever gypsum was present, is then gently poured into another cup or can *A* without removing any more of the powder than absolutely necessary. The undissolved powder is then dried in the cup and heated to a dull red, after which it is allowed to cool and again boiled with water as before, in order to dissolve the decomposed alunite. After the remaining powder has settled the clear water is then gently poured off into another cup *B*.

A small portion of the barium chloride is now dissolved in a little water, which should give a clear solution or be only very slightly clouded. The water in both the cups *A* and *B* is heated nearly to boiling and some of the barium chloride solution added to each. If either solution becomes cloudy it is proof of the presence of sulphates. If *A* is clouded and *B* remains clear, the rock contains gypsum but no alunite, while if *B* is clouded and *A* remains clear, alunite is present without gypsum.

In the arid regions of the West and Southwest the waters frequently contain sulphates, and this, it is feared, may prove the chief source of trouble in the application of the method. In any case it is always well to test the water before going to the trouble of preparing the rock powder. Take a little of the water in a cup and add a few grains of the barium chloride; if more than a very slight milkiness is produced this water cannot be used in the determination, since the sulphates in it would prevent the detection of those in the rock.

When suitable water can be procured any prospector can easily and quickly apply these tests after a little practice. Thus he may know positively whether or not alunite is present, and if it is he may prepare to sink deeper with a reasonable expectation of finding gold also. A rough estimate of the amount of alunite present may be made from the quantity of precipitate that clouds the water in *B* when the barium chloride solution is added. In making these tests it should be remembered that alunite is insoluble in either hot or cold water, and that it is decomposed and made soluble only when it is distinctly heated to a dull red. Care must be taken, however, not to heat the powder to a bright red, as this would drive off some of the sulphur trioxide which is

easily recognized by its pungent odor. When this happens a fresh sample should be taken and another test made.

A Triangulation Station

By LEE FRASER*

For purposes of triangulation the chief requirements of stations consist in permanency and proper location, so as to be at all times visible. After considerable experience in surveying where the underbrush and forest growth is dense, a triangulation point, properly located, and constructed in the following manner was found to give satisfactory results:

The bill of material for one station consists of the following: 48 in. of 2¼-in. galvanized iron pipe; 8 in. of 1-in. brass or copper tubing; 72 in. of ½-in. round iron; 14 ft. of 1¼-in. galvanized iron pipe; 1 reducer, 2¼x1¼ in.; 40-ft. wire; 1 target; 100 lb. portland cement; 1000 lb. crushed stone, and three 2-ft. wooden stakes. The total time required by two men, for the construction of one station was two hours, all the material being on the ground with the exception of the stone, which was gathered from the hillside, and water, which was procured from a nearby stream.

After excavating a hole of proper dimensions, the 4-ft. length of 2¼-in. pipe reinforced by six 12-in. lengths of ½-in. round iron, is placed upright in the hole, and concrete (1-10) tamped firmly around it. Especial care must be taken in securing the pipe in a truly vertical position, for upon this condition, is dependent the verticality of the flag. After placing the base pipe (Fig. 2) in position, the interior is filled with concrete to within 10 in. of the top, and thoroughly tamped. The pipe is next filled with mortar to within 3 or 4 in. of the top, when the 8-in. brass or copper center, open at the bottom, but brazed at the upper end, is inserted in the mortar and thoroughly worked up and down to cause the mortar to pack firmly in the tube. It is then set with the upper end 1 in. below the end of the large pipe, insuring ample protection to the surface upon which the center mark is inscribed. Upon careful centering of the copper center tube the horizontal difference from coincidence between the axis of the flag and the center mark must be slight, and of so little importance as to be sufficiently accurate for the great majority of purposes. When the main pipe is thoroughly set, the attaching of the flag is a simple matter.

The flag being gray is readily distinguished against almost any background and especially against forest growth.

*Mining engineer, Aguacate Mines, San Mateo, Costa Rica, Central America.

When there is probability of confusion of the stations with one another, an excellent mark, and possessing the advantage of being distinguishable from any paint, is some geometrical figure, such as a sphere, a cone or cylinder made of wood and placed upon the top of the signal. When the pole is liable to incline, due to

FIG. 1. TRIANGULATION STATION AND METHOD OF CONNECTION

FIG. 2. BASE PIPE OF TRIANGULATION STATION

heavy winds, it is well to attach guy wires to insure rigidity, but it is exceptional when this measure must be used. To facilitate observations for elevation, a red and white band is painted about the pole, the junction of the two colors being a certain known distance above the station.

Copper Mines in Chillagoe District, Queensland

Some Isolated Properties in Northeastern Australia where Small Scale Smelting Operations Have Been Successfully Conducted

BY GERARD W. WILLIAMS*

In addition to the copper mines of Chillagoe already described in my previous article on "The Mining Industry in Queensland," in the JOURNAL of March 20, 1909, there may be cited some other copper properties of this northern sec-

tioned and a brief description of its operation will be given, but before proceeding with this account, attention will be directed to the accompanying illustrations of the lead and copper smelting plant of the Chillagoe Railways and

the Cairns-Chillagoe railway line. The country consists of slates and sandstone with intrusions of acidic rocks. The lode channel itself follows the course of a dike of felsophyre which can be traced for a considerable distance across the

GENERAL VIEW OF LEAD AND COPPER SMELTING PLANT AT CHILLAGOE, QUEENSLAND

HUNTINGTON-HEBERLEIN ROASTING PLANT OF THE CHILLAGOE COMPANY

tion that are examples of small scale smelting operations successfully carried on at mines that are some distance from the railroad. The O. K. mine and smeltery have already been described. In addition, the Mount Molloy mine may be

Mines, Ltd. The complex ores contained in this company's properties and the reduction works were described in the previous article.

THE MOUNT MOLLOY MINES

The Mount Molloy copper mine is situated 20 miles north of Bibboorha on

surface of the country. The ore is comparatively low grade and is sorted in the stopes. The mining practice presents no particular points of interest. The smelting plant comprises a water-jacket furnace, 90x36 in. at the tuyeres and 10 ft. 6 in. to the feed floor. The matte gravitates to a reverberatory where it is

*Consulting engineer, Stock Exchange Club, Melbourne.

kept warm till such time as it is wanted by the converter. The output is insufficient to keep the converter continually in action so the converter plant only runs two shifts and the night shift matte is stored in the reverberatory furnace. This method appears to be more expensive than the O. K. mine practice where mattes produced on night shift are returned to the furnace in the morning.

The analyses in the accompanying table indicate the nature of the ores treated.

1; coke, 2. The furnace treats about 130 tons of charge per day exclusive of coke. The slags average: SiO_2 , 39.9 per cent.; FeO , 30.4; CaO , 9.9; ZnO , 6.5; Al_2O_3 , 8.0; MgO , 3.2; S, 0.7; Cu, 0.43. The mattes produced average 50 per cent. copper.

The presence of zinc in the ore is by no means a favorable indication, for thus far mines in North Queensland which contain zinc have failed signally to develop well in depth. This mine has

a few miles of the camp and the immediate neighborhood of the mine is well-grassed, park-like country. The company owns large timber concessions and is opening up a large export trade in timber. With the gradual depletion of the more available timber supplies the Queensland timber must come into considerable demand. One of timbers obtained here, the crowsfoot elm is equal if not superior to the best hickory or ash for the making of pick or ax handles, and for mining purposes the spotted gum is largely used. Cedar, pine and Morton Bay ash are shipped to the southern states.

EINASLEIGH COPPER MINE

This promising mine is situated about 110 miles south of Chillagoe. The lode occurs in black mica schists lying on the contact of granites. The mine has been opened up to 300 ft. in depth and developments are satisfactory. Some time ago, the company attempted blast-furnace smelting with charcoal but the attempt was not successful. The advent of the new Ethridge railway, however, will enable coke to be obtained at a reasonable price. Unfortunately the mine promises to be highly silicious and concentration methods will have to be adopted as there is no iron flux obtainable locally. The outcrop is almost entirely covered by a flow of basalt of Tertiary age. The only portion visible is in the bed of the river where the waters have cut through the basalt sheet and have exposed the older rocks beneath.

Around the Einasleigh the country is covered with this basalt flow, but about 35 miles away a large copper outcrop has recently been discovered. It is of considerable extent and richness. Other small prospects have recently been opened, the new railway from Chillagoe to the Ethridge having given a great impetus to prospecting of all descriptions. The great need of northern Queensland is railways and it is to be regretted that there is such strong opposition to the building of private lines. The labor-democratic party opposes all lines owned privately and the state is not in a position to construct purely experimental lines from the public funds. If private enterprises were given a free hand the whole northern country would be speedily opened up, to the ultimate advantage of the state. But Queensland like the rest of Australia suffers from over-legislation and largely at the cost of the mining industry, which appears to be especially selected for experimental legislation.

COPPER MATTING FURNACE OF THE CHILLAGOE COMPANY

ANALYSES OF MOUNT MOLLOY ORES.

	Chalcoprite Ore.	Semi-sulphide Ore.	Carbonate Ore.	Pyrite Flux.	Iron Flux.
SiO_2	33.7	58.1	64.7	12.8	12.1
FeO	20.6	10.4	4.8	70.6	70.6
Al_2O_3	3.7	7.8	3.2	12.1	12.1
CaO	1.1	1.1	1.1	1.1	1.1
MgO	6.7	3.3	3.3	3.3	3.3
ZnO	7.7	3.3	3.3	3.3	3.3
S	10.7	3.5	4.5	4.5	4.5
Cu	7.7	14.1	11.1	12.1	0.5

The charge is made up approximately as follows: Chalcoprite ore, 10 cwt.; pyrite flux, 4; semi-sulphide, 1; iron flux, 3; limestone, 2; fine dust, 2; converter slag,

attained a depth of 430 ft. but the ore body is smaller at that depth and appearances generally are not very favorable. The Mt. Garnet copper mine in the Koorboora district started off well but shortly after smelting operations started and about the time that the railway was extended 35 miles to the mine, the copper ore passed into zinc ore and the mine closed down. In depth the zinc seems to entirely replace the copper or it may be that the copper is really only a secondary replacement of the zinc blende.

Unlike most mining camps this mine is situated in the midst of beautiful country. The great tropical forests of the coastal range come down to within

Sheffield University, England, is installing an electric-steel furnace of the Kjellin type, to be used for experimental purposes.

The Gem Bearing Pegmatites of Western Maine

Deposits, Operated by Open Cut, Produce Tourmaline, Beryl, Feldspar and Mica. The Gems Occur Principally in Pockets in the Narrower Dikes

BY W. ROGERS WADE *

The discovery of tourmaline in Maine is credited to two students, Hamlin and Holmes, who were gathering specimens near the town of Paris in western Maine, in the autumn of 1820. Some crystals of green tourmaline were found, with which they were not familiar, and the specimens were sent to Professor Stillman of Yale for identification. In those days tourmaline was not used as a gem stone and the deposit was regarded as a mineralogical storehouse only. It was not till 1880, about 60 years after its discovery, that this deposit, now widely known to mineralogists as the Mount Mica mine, was opened as a mining property. So far as I can learn, this was the first gem deposit of value discovered in the United States.

THE PEGMATITE AREA

The area of granite pegmatites extends in a general northwest direction from the Kennebec river in Maine to New Hampshire. They compose a broad band of country 25 to 30 miles wide and occur as parallel dikes and sills between the bedding of older schists, gneisses and limestones. But few of these pegmatites are gem bearing and it is the purpose of this paper to treat only of those that are. The section in which the gem-bearing pegmatites occur extends from Auburn to Newry, Me., an area about 70 miles long by 15 miles wide, and near the center of the larger zone. Their general strike is northwest and the average dip between 10 and 20 degrees to the northeast. They occur in connection with large granite areas.

The southwestern side of the belt is flat or slightly rolling country, and the valleys are filled with glacial sands. On the northeastern side the country is hilly with many rock outcrops. The pegmatites themselves, while they are easily disintegrated, do not weather away as fast as the mica schists above them. As a result their outcrops often form long low bluffs as at the Pulsifer and the Maine Tourmaline Company's mines in Auburn. They are more apt to outcrop on the hillside than on its very top. The Mount Mica mine is an exception to this.

CHARACTERISTIC COARSE STRUCTURE

The most pronounced feature of the pegmatites is their coarse structure. Quartz crystals 2 to 3 feet in diameter are encountered, while feldspar crystals weighing a ton or more are met with. Some

of the pegmatites not carrying enough tourmaline to be of economic value are often so rich in bands and masses of feldspar that they are mined for that mineral, which is ground and used in the manufacture of pottery. Large beryl crystals are apt to occur in these feldspar mines. One beryl crystal, encountered at the Berry mine in Poland, Me., was reported as being 6 ft. in diameter. At Buckfield in a tourmaline mine, quartz crystals are found so large that two men cannot lift them.

Another absolutely essential characteristic of gem pegmatites is that they shall be rich in lithia minerals. This is due to the fact that gem tourmaline must have at least one half per cent. lithia among its bases. The lithia minerals, especially lepidolite, concentrate around the pockets or gas cavities in which the gems occur, and are used by the miners as indicators that they are nearing a pocket.

These dikes all show a banded structure. Next the hanging-wall is a medium-grained band about as coarse as ordinary building granite, called graphic granite. This consists of a feldspar ground-mass with lens-shaped quartz crystals, distorted by flowage while cooling, and a small amount of biotite mica. Below this occurs the zone of huge crystallization. In it are great mica plates, quartz masses and crystals, and masses of soda feldspar or albite. In the lower part of this zone, and often at the juncture with the one below, occur the gem pockets, lepidolite and practically all the rare minerals. It is locally called the "mineral sheet." Below this comes a band of nearly pure potash feldspar. On the underside of this feldspar, where it joins the next zone, is a narrow band of garnets from one to two inches thick. This is called the garnet streak and marks the lower edge of the vein commercially. The next zone below this is another biotite graphic granite, under which is the footwall.

ASSOCIATED MINERALS

A complete list of all the minerals found in these pegmatites counting those of rare occurrence would run into the hundreds. The most common besides the quartz, feldspar, and mica which compose the bulk of the dikes, are cleavelandite, lepidolite, black tourmaline, lithia or gem tourmaline, beryl, apatite, spodumene, caesium beryl, compounds of tin, manganese, triphylite, lithiophilite, beryllonite, caelite, hertrandite, montmorillonite,

topaz, garnet, zinc spinel, herderite, and a host of the rarer minerals occur sparingly.

The only gems suitable for cutting in these deposits are tourmaline and beryl. The tourmalines are red, blue, green, white or pink, the red and green shades being the most desirable. Often several colors are found in the same crystal, varying from tip to tip or from the center outward. The beryls are either white, blue or yellow in color. The white beryls are brilliant when properly cut, but having no distinctive color are not much used in jewelry. The same is true of the white tourmaline. The blue beryl, called aquamarine, is, however, extensively used, also the yellow or golden beryl to a lesser extent. The large beryl crystals are generally opaque and of the characteristic pale apple green color. The tourmalines are found in pockets, but the beryls are usually embedded in the "mineral sheet."

ORIGIN OF THE DEPOSITS

These pegmatites have been intruded between older metamorphosed rocks. The larger fissures and stocks have been filled with the original granite magma, while in the smaller fissures the magma has become more acid, due to the greater ease with which vapors and superheated steam traversed these narrow openings. These vapors consisted of fluorides and borides of silicon, volatile compounds of iron, manganese, and the alkalis, with superheated steam. By this differentiation, the magma in the smaller openings came to have a greater percentage of gases, vapors, and steam than the original granite magma. Also the larger bodies, cooling more slowly than the small dikes, continued to give off acid vapors which passed, through cooling cracks and open channels in the center, into the smaller dikes as these became partly solidified.

In the smaller of pegmatite masses, the material next the walls was cooled and solidified rapidly as graphic granite. This caused a concentration of the vapors in the center of the dike. These vapors and steam reacting, finally changed borides and fluorides of silicon partly to quartz, which deposited as a secondary coating in the pockets, the hydroboric and hydrofluoric acids combining with the alumina of the feldspar and with lithia to make the gem tourmalines. Later solutions caused the alteration of the tourmalines in some of the cavities to cookeite.

It is seen that this hypothesis, if true, explains why the larger dikes make feld-

*Mining engineer, Tyrore, N. M.

spar mines and the smaller ones gem mines, because in the former there was not sufficient acid vapors concentrated to produce much tourmaline.

MINING TOURMALINES AT AUBURN

The Maine Tourmaline Company's mine at Auburn is situated three miles from the railroad, on the southwestern side of Mount Apatite. An electric car line from Lewiston to Mechanics Falls passes within one-half mile of the workings. The pegmatite outcrops in a meadow and a gentle hill slopes back from the vein to the northeast. The outcrop is a low bluff 5 to 10 ft. high. The dip is 7 deg. to the northeast and the strike is north 50 deg. west (magnetic). Both foot- and hanging-wall are brown mica schists. Two trap dikes, from 4 to 6 ft. wide, standing vertically and striking northeast, cut the vein but have had no effect on the deposit. The upper graphic granite is 4 to 6 ft. thick, the "mineral sheet" is from 2 to 5 ft. thick and the feldspar zone below it is about 2 ft. thick on the average. The lower biotite graphic granite is about 8 ft. thick. All mining, however, stops at the upper edge of this zone at the garnet streak.

The mine is worked by three open cuts, the largest of which is 30x50 ft., with a depth of 14 ft. The rock is broken as follows: a row of 10 to 14 holes from 6 to 10 ft. deep is drilled with a steam drill in the mica schist and graphic granite, and fired by electricity, using 40 per cent. dynamite. This exposes the "mineral sheet" which is taken out carefully with 2- to 4-foot holes loaded very lightly and fired singly by fuses. In case a pocket is approached great care is taken not to place a hole too near where it is supposed to be. The rock next the pocket is removed with a pick or moil.

APPROACHING A GEM POCKET

The miner knows when he is nearing a pocket by the following changes in the "mineral sheet." First, the albite changes to cleavelandite. Next, a very curious rock composed of quartz and black tourmaline having the structure of graphic granite is encountered. The tourmaline crystals are all parallel plates or lenses and seem to have been stretched while cooling if they were formed from a fluid magma. They are so close to the pocket, however, and the quartz appears so very much as if it were water deposited, that it is likely that both the quartz and tourmaline crystallized from hot acid aqueous vapor and that the surrounding crystallographic relations were such that the tourmaline was forced to crystallize in one plane.

After the black tourmaline and quartz, lepidolite makes its appearance and runs to the pocket. There is often standing over the pocket large plates of muscovite with radial opaque pink or green tourmaline crystals intergrown between the mica

plates. The muscovite often changes on its lower edge to lepidolite when the plates extend into the top of the pocket. Sometimes this lepidolite border will go all around the muscovite plate. I observed one diamond-shaped muscovite plate a foot across with a 4-in. rim of lepidolite around it.

Quartz of a smoky hue is generally associated with the large mica plates. The upper half of the cavity itself is generally quartz, mica and cleavelandite, the lower half being a porous decayed potash feldspar. The quartz, mica and cleavelandite growing into the top of the pocket are all beautifully crystallized. Pink and green tourmaline crystals are often grown into these quartz points. Most of the gems, however, lie in the mud or clay which partly fills the lower half of the pocket. Though many crystals are broken or badly flawed, others are perfect.

Many of the pockets contain no gems or apatite and are locally called "dead pockets." When an excessive amount of lepidolite occurs around a pocket it will be found to contain apatite with little or no gem tourmalines. It seems as if all the lithia was consumed by the mica and none left for the gems. In fact black tourmaline in small crystals is sometimes found in these pockets, which would beyond doubt have become gem or lithia tourmaline could they have secured the lithia.

BARREN POCKETS

The quartz crystals in the gem or apatite pockets are always coated by a thin secondary growth of minute quartz crystals. The quartz crystals of the "dead pockets" have no such coating. This would seem to indicate that the quartz crystals formed first. Then vapors of silicon fluorides, as perhaps the tetrafluoride, and similar vapors and compounds of boron, entered the pocket and meeting superheated steam, were oxidized to silicon oxide, freeing hydrofluoric and boric acids. These acids attacked the feldspar at the lower part of the pocket and with the lithia, which was present or came with the vapors, formed the complex borosilicate of alumina and lithia which is gem tourmaline. The latter contains 1.59 per cent. lithia and 0.29 per cent. fluorine, while the black tourmaline contains but a trace of lithia and no fluorine. Also the black tourmaline contains much less alumina and makes up this deficiency by increasing the ferrous oxide from 0.26 per cent. to 1.428 per cent.

In the "dead pockets" the fluoride and boride vapors of silicon never entered and tourmaline was not formed. They are apparently nothing but dead steam cavities, with only bright white or smoky quartz crystals projecting into them from the "mineral sheet" above, and have no secondary coating. The feldspar at the bottom of these pockets does not show the

porous structure and decay of that of the gem pockets.

There is another kind of pocket in which the quartz crystals are coated with the secondary growth, but the tourmalines will be mostly altered to cookeite mica, only small portions of large crystals remaining. These cookeite pockets are generally dry or bony, that is, little if any wet mud or clay is present, dry hard cookeite mica taking its place.

A curious thing has been noted at this mine in connection with the gem beryls. A beryl crystal having a black tourmaline crystal next to it or growing into it, is always clearer and of a deep aqua-marine blue and cuts better gems than a beryl crystal not so accompanied. The feldspar from the third zone and all mica whether scrap or plate mica, are saved for market at this mine.

The Maine Tourmaline Company's mine yields principally pink and green tourmaline, the deep red shades not being abundant. Some very beautiful deep green stones of good size have been recovered. In 1904 a series of pockets yielding handsome dark blue tourmalines of nearly an oriental sapphire shade, were opened in pit No. 2. The green tourmalines from the Maine deposits are superior in color and brilliancy, especially at night, to those found in Brazil or California, and when properly cut are exceedingly beautiful gems.

The cost of mining per ton of rock removed for the years 1904 and 1905 was as follows:

Labor, 28.3c.; fuel, 2.3; explosives, 5.9; repairs, renewals, oil, etc., 0.4; total, 36.9. This does not include superintendence or office expenses.

OTHER MINES

The Pulsifer mine is on the same vein as the Maine Tourmaline Company's property at Mount Apatite. It was opened in 1901 or 1902 and has only been worked in a small way by an open cut about 15 ft. long and 10 ft. wide. This property produced a notable pocket of clear, transparent, purple apatite crystals, of which there were nearly 3000 in the pocket counting all sizes, the largest of which were about 2 in. in length. A large part of this find was purchased by Harvard University and is now in their museum. The occurrence of the tourmaline is the same in this mine as in the mine previously described. The predominating shades are pink and green, and many fine crystals have been taken from this small excavation.

For the last two years the John S. Towne lease has been subject to the Maine Feldspar Company which did the mining, using a steam drill and derrick to handle the waste, paying a royalty on the feldspar and leaving the gems to Mr. Towne. Green tourmaline of a value of about \$1500 was recovered during the

summer of 1907. The deposit is a continuation of the Maine Tourmaline Company's vein, but the dike is much thicker here and contains a greater amount of feldspar. The property is in the class between the straight feldspar mines and the straight gem mines.

The Hatch mine was opened in 1882, near the top of Mount Apatite, on the southeastern slope. The property has been worked spasmodically since. The principal product has been feldspar, the only tourmaline coming from a small open cut where the mine was first opened. The general character of the ledge is similar to those already described except that the dike is very thick. The hanging-wall has been eroded away and the footwall is not exposed to view.

THE BERRY MINE

The Berry mine, strictly speaking, is not a gem mine, its main product being feldspar. It is situated about two miles south from Mount Apatite. Here cleavelandite is not common, the feldspar being mostly orthoclase. The pegmatite is of immense size and glacial drift hides the wall rocks. It is not possible to tell the shape, dip or strike of the deposit. Both pink and green tourmalines of gem quality are occasionally found. Some good gems have come from the mine, but gem material is not abundant enough to warrant working it as a gem property. Both apatite and hercynite are found here. Gem pockets occur in the orthoclase with only a small amount of mica and quartz around them. Lepidolite is always present. The mine has been opened as a large quarry and hand drilling is used entirely.

In the township of Hebron, about 16 miles northwest of Mount Apatite is the Merrill mine. The vein is 12 to 14 ft. wide with mica schist walls. Very little work has been done here. The occurrence is similar to that at Mount Apatite. The deposit has produced some of the deepest red tourmalines I have seen.

The Mount Mica deposit was discovered in 1820 as already mentioned, and the locality is famous for the gems and minerals it has produced. Active mining began in 1880 and has been carried on ever since. Mount Mica is a low hill in the township of Paris, Me., and is 26 miles from Mount Apatite. The pegmatite here is about 20 ft. thick, lying nearly flat between brown mica schist walls. Graphic granite exists next both walls, with the "minerals sheet" and feldspar zone between as at Mount Apatite. The mine is on the top of a gentle hill and is worked as a large open quarry about 200 ft. long by 100 ft. wide by 20 ft. deep at the deepest point. Drilling is done by hand and the waste rock piled behind by a derrick as the quarry advances. One pocket in this mine was of unusually large size, being 6 ft. high, about 12 ft. wide and 20 ft. in length. As is generally the

case with very large pockets it contained few gems. The medium sized pockets, 2 to 3 ft. in diameter are the best producers.

THE NEWRY DISTRICT

The National Paper Company owns a piece of land in Newry, near North Andover, Me., on which tourmalines were found in 1902. The property seems to be fairly rich but due to the peculiar occurrence of the gems, they are difficult to recover. The pegmatite seems to be more or less uniform throughout and lithia minerals, especially triphylite, are abundant. The lepidolite does not segregate around pockets here, but comes sprinkled through the vein in small quantities. The gems occur in the solid rock just as a horblende crystal would in granite, only of course not so abundantly. There are certain spots where the texture of the ledge is coarser and the better gems are found there.

The gem crystals are peculiar in themselves, for they nearly all consist of two crystals crossed obliquely. They are generally opaque and of a faint apple green color on the outside with a beautiful, clear, red or green center. What the form of the deposit is I am unable to say as I obtained my description of the mine from Loren B. Merrill, manager of the Mt. Mica mine. This Newry deposit is about 70 miles from Mount Apatite, in a north-westerly direction and is on the end of the belt, as far as has been proved.

Metallic Chromium

Although chromium has long been known, it was not until the advent of the electric furnace that it was produced in a solid mass. Previous to that time it was obtained only in powder or fine crystals. According to the *Brass World*, May, 1909, solid, massive chromium is now obtained commercially in two ways: (1) By the so-called aluminothermic method; (2) by means of the electric furnace.

The aluminothermic process consists in reducing the oxide of chromium by means of aluminum. The reaction which takes place supplies heat enough to melt the chromium. By adjusting the proportion of oxide of chromium and aluminum it is possible to obtain fused, metallic chromium of high purity by this process. It is free from carbon.

In the electric furnace process, oxide of chromium is heated with carbon by means of the electric arc and the chromium is then reduced to the metallic state. When thus made it is combined with a large percentage of carbon, and requires purification. To remove the carbon, the crude chromium is melted with lime in an electric furnace. The carbon combines with the calcium to form calcium carbide, and the pure chromium is obtained as a fused mass.

By either of these processes, it is possible to obtain fused, massive chromium of a purity of from 97 to 98 per cent. metallic chromium. It does, therefore, compare favorably in purity with ordinary commercial metals.

Jones Iron Furnace

In U. S. Pat. 12,928, March 16, 1909, assigned to the Jones Step-Process Company, John T. Jones, of Iron Mountain, Mich., illustrates an improved furnace similar to that previously patented by him (U. S. Pat. 866,280, Sept. 17, 1907). The furnace is designed for smelting iron ore containing slag-making constituents which become fluid at a temperature not exceeding 2300 deg. F., a lower temperature than is necessary to melt the reduced iron of the ore. A vertical sectional elevation of the furnace is shown in the accompanying

JONES IRON FURNACE

panying illustration in which the upper portion of the ore stack is broken away. The furnace consists essentially of a separate fuel-burning furnace *F* and an ore stack *A* with a chamber beneath the latter for the separation of the unmelted material and the molten slag.

The stack *A* is charged with ore in a finely pulverized condition mixed with a refractory material such as coke. The charge spreads out at the base of the stack as indicated by the dotted lines *B*. The reducing gases from the furnace pass around and through the ore column reducing the iron oxide to metal, the molten slag accumulating as a bath in the bottom of the chamber. When it has reached a depth indicated by the horizontal dotted line *C*, it is tapped off through the slag hole *D*. At *E* are horizontally operated rams which force the unmelted material through discharge openings on the opposite side. The metal is then separated by crushing and concentrating, or otherwise.

Features of a Vein Formation in Nicaragua

The Vein-System and Orebodies Appear to Be the Result of the Fracture and Decomposition of Effusive Rocks, Their Tuffs and Breccias

B Y H. E. W E S T

The purport of this paper is to portray the typical features of a vein system situated in the Matagalpa district of Nicaragua. The explanation offered makes no pretense to being authoritative; on the contrary, it is a simple record of observations such as are necessary to the intelligent exploitation of any ore deposit. From the general topography of the locality it is apparent that the structural geology is a manifest of its volcanic nature. This inference is supported by: (1) The abruptly broken topography of the entire area; (2) the effusive overflows exposed on the high summits, mostly basalt tuffs, and breccias; (3) the rhyolite sheet in the low ground, with its several conical hills (this sheet has a strike almost east and west, and extends for several miles); (4) the andesitic-breccia south of the vein, with amygdaloidal sheets, andesite or possibly diabase.

In brief, the entire region, with an altitude of 2000 to 3000 ft. above sea-level, is composed exclusively of volcanic ejectamenta and lava flows. It would appear as if, for the most part, the central and western portion of Nicaragua, at surface, were composed of extrusive rocks. The deep-seated granite, diorite, and allied rocks, are absent, although possibly occurring and visible outside the influence of the more recent outflows. Sedimentary rocks appear to be entirely absent, although, some distance from the mine, there are said to occur small deposits of limestone.

Central America generally is noted for its products of vulcanism, and possesses several active volcanoes. In Nicaragua there may be half a dozen volcanoes still active, of which Momotombo, near lake Managua, is the most active. After enjoying a period of ten years of comparative quiet, during 1904 this mountain was the scene of a very active eruption. Bombs were hurled, it is claimed, thousands of feet in the air; dust settled on the neighboring cities, while streams of lava flowed to the base. The detonations from the crater were plainly heard in Matagalpa, a distance of 90 miles.

VEIN MATTER

Speaking generally, the valuable part of the vein consists of bands of vesicular quartz with a filling of soft manganese oxide and clay. The width of this ma-

terial varies from a foot to possibly 20 ft. in places, having an average thickness of 3 to 4 ft. Bordering this on one or both sides, is often a brecciated wall-rock, cemented by quartz; which quartz, usually in crystalline form, radially surrounds the inclosed fragments. This friction breccia is often drusy and contains many beautiful quartz-lined vugs. The brecciated portion is invariably of low grade. From the open nature and porous structure of the vein, there is, as might be expected, a free circulation of groundwater; which accounts for the thorough oxidation and for the presence of a quantity of a red unctuous clay, occurring as a "gouge" against the walls, and also filling joints and interstices.

strongly in evidence as far as 1300 ft. in adit No. 1, where it leads to a wide lens of ore; for the entire distance its presence is associated with the enrichment of the vein. Thence to the present end, almost 2000 ft. to the breast, this dike alters materially, and, in places, is not even apparent. It loses its distinctive color and is more open in texture, but it is still plainly fragmental; chert, with pyrolusite and psilomelane are marked associates. Coincident with this change is an impoverishment of the vein.

In Fig. 3 are shown sections of adit No. 1 at 620, 900 and 1850 ft. respectively. The view at the left is a normal exposure of the vein in the breast at the western end; in this, the dike, the vesicular quartz-bands and the included

FIG. 1. SECTIONS AT CROSSCUTS IN ADIT NO. 1 AND ADIT NO. 2

Outside the zone of brecciated wall-rock, as shown in Fig. 1, there extend in some instances, what might be termed "quartz-droppers," having a dip of about 60 deg. These droppers enrich the country, but rarely enough to make the rock profitable to mine.

A noteworthy feature is the presence of a blue-green rock, very hard and tough, usually impregnated with pyrite, and to a certain extent with zinc and lead sulphides. This rock, which has the appearance of being formed from fragments filling a fissure, cemented and hardened by silicious waters, may, therefore, be termed a clastic or fragmental dike, and I shall so designate it. This occurrence is found on the footwall side of the manganese section, and immediately contiguous to that part of the vein. The dike is never very wide; it varies from a few inches to 4 ft. It is

manganese ore are plainly shown. The soft north wall and the shaly hanging are also typical. In the center view the hard firm footwall is the elastic dike, while the hanging is shown extremely broken, an evidence of its weak, slabby nature. The roof is composed of the volcanic breccia, which is here remarkable for the brilliance of its coloring. The blue of crysocholla, the green of malachite, the brick-red of iron peroxide are mingled with the lighter shades of mauve, pink and yellow, and scattered through the mass are fragments almost pure white, usually roughly rectangular in section. Some of the constituents, such as the light-blue rock, are in masses 3 to 4 in. in diameter; but, for the most part, the fragments are small, usually from $\frac{1}{4}$ to $\frac{1}{2}$ in. in diameter. Toward the eastern end of the adit the elastic dike gives place to a more coarsely

*Mining engineer, El Oro, Mex.

fragmental rock, in which particles of chert are prominent; and, in addition some of the harder forms of manganese oxide, such as psilomelane, the hydrated oxide (with its conchoidal fracture) and also pyrolusite (of fibrous texture), and probably some manganite.

ENRICHMENT OF THE COUNTRY ROCK

An interesting example of the alteration of wall-rock to ore, either by replacement or impregnation, is shown in Fig. 2. Here we have the direct conversion of practically barren country with gold to the amount of 20c. per ton, being enriched to ore of \$5.20; the physical appearance is changed, as also its chemical composition, in part due to the deposition of manganese oxide. Probably impregnation rather than molecular replacement, would be the more justifiable interpretation. The occurrence of small unaltered cores is interesting, showing

each side, with brecciated wall-rock cemented by quartz, and manganese oxide with included country. On the right in Fig. 4 is shown a sketch of the cross-cut in the south wall, inside of a vein enlargement. This inner section contains but 80c. per ton in gold, and is, therefore, but slightly enriched; and it is plainly evident that this enrichment is due to the veinlets filling numerous fractures that seem to conform roughly with the large joint planes of the basaltic country. The arrows show that these slips cross one another, forming blocks. It would appear as if this were one of the earlier stages of ore formation following the first steps of decomposition along the joint planes. On the other hand, as the orebody seems to favor the softer breccia, by the alteration of which most of the ore appears to be formed, it is equally possible that this may be read as an example of the defini-

tion with the quartz, and the silver with the manganese. A sample was panned, washing off the manganese and clay, and the concentrate assayed. The results tend to confirm the assumption that the gold content is confined largely to the environment of the quartz, and the silver to the manganese portion. The occurrence of gold is mostly free, although very fine and rarely visible. The gold particles are, however, not readily amalgamated, owing probably to an enveloping film at present unascertained. There would appear to be evidence of a thin quartz seam comparatively rich in gold, and, at times, in native silver, passing through the richer portions of the vein.

There is a marked decrease in the silver content of the manganese ore in the eastern part of the mine. The gold content is more pronounced and the orebody wider when the vein passes through the soft porphyritic country, presumably a softened and altered andesite, which accompanies the vein from about the 600-ft. to the 1600-ft. mark. From this point east within the harder basaltic country the vein is both smaller and poorer; so that, generally speaking, the low parts of the contour may be regarded as more favorable to ore formation.

Another marked feature is the large amount of clay, the work of the groundwater on the soluble silicates of the vein walls. This clay is usually of a banded and fissile structure, often red and black alternating, so that when sun-dried, the mass falls to pieces with a distinctly conchoidal fracture, resembling the leaves of a crumpled book. A sample was dried and assayed, it gave \$2.40 in gold and no silver. Generally speaking, the ratio of silver to gold in the deposit is as 1 to 10, allowing 50c. per oz. of silver.

The Engineering & Mining Journal, N. Y.

FIG. 2. ALTERATION OF WALL ROCK TO ORE BY FISSURING, SILICA INFILTRATION AND MANGANESE IMPREGNATION

how some of the wall-rock has resisted the encroachment of the circulating manganese-charged waters.

It would also appear as if, previous to the impregnation by manganese-bearing solutions, the wall-rock had been rent and subsequently filled with quartz, crystallizing out of deep-seated waters. These solutions were presumably low in manganese, as the quartz-filled fissures in the wall-rock usually contain but a filling of yellow clay, the alteration products of the feldspars. Fractures, possibly of another period from those forming the quartz veinlets, bearing manganese on their exposed faces, afford support to the hypothesis suggested.

At the left in Fig. 4, the roof of adit No. 2 presents a representative structure; there is the soft black wad on

tion of the orebody, the basalts not favoring metamorphism to ore.

Referring again to the section of the roof shown in Fig. 4, the gold and silver occurrence is noteworthy; here, again, the richest ore occurs in the dark manganese, the brecciated section being practically barren, and the included wall-rock carrying but a trace of either metal. The breast of adit No. 1, at 620 ft., in Fig. 3, is typical of a section showing some of the higher gold contents. This is usually the case when the vein has a banded structure with included manganese. It will be noted that the elastic dike is poor

DISTRIBUTION OF THE METAL

From several experiments, I concluded that the gold is more intimately associated

with rock fragments. It would appear that we have to account for one or more rock fractures; wall brecciation; a fragmental filling; silicification; and contemporaneous or subsequent impregnation by manganese, with gold and silver enrichments. Doubtless, the volcanic nature of the entire formation will satisfactorily account for the agency producing the primary rock fracture and wall brecciation, and also for any subsequent fracture and its filling with rock fragments.

The comminution of the rock faces by subsequent movements would account for the wider breccias; also the coursing through of deep-seated silicious thermal waters, which, in cooling, formed the cementing medium of this breccia. The latter breccia is very distinct from the silicified fragmental filling previously mentioned. The latter has an open texture and is full of vugs; the quartz, moreover, is crystalline and arranged

radially to the inclosed fragments; whereas the former is a dense, hard, blue-green rock, with the fragmental portions often all but undiscernible, and usually impregnated with metallic sulphides. Through the more open channels, due to the suggested secondary rock movement, there would appear to have been introduced circulating waters rich in manganese, the elastic dike to the north forming both an impenetrable barrier and acting as a guide to the manganese-enriching waters.

The question arises, whence came these large quantities of manganese oxide? It

tremely permeable, and therefore the water circulation may be taken for granted as being both vigorous and comprehensive. Professor Kemp says, "In regions of expiring volcanic activity, waters may be expected at comparatively any reasonable depth and, therefore, comprehensive circulation of deep-seated waters may be expected;" and again in regard to sources whence circulating waters derive the elements of ores and gangue, "The generally accepted theory is that they are gathered from a condition of extremely lean dissemination in the rocks through which the underground waters

tions they at times assume, these deposits are in the first place gathered from the complex silicates that are components of volcanic rocks. These minerals are soluble in both mineral and humus acids, such as occur in acidulated meteoric waters containing traces of sulphuric and carbonic acid; and probably are first altered to the carbonate, thence to the hydrous oxide whence is derived the dehydrated form, as in hematite and pyrolusite. With regard to their sulphides, those of iron are of common occurrence, as pyrite, marcasite and pyrrhotite, while the manganese sulphide,

FIG. 3. SECTIONS ON ADIT NO. 1 AT 620, 900 AND 1850 FEET, RESPECTIVELY

FIG. 4. ROOF OF ADIT NO. 2 AND CROSSCUT SHOWING TABULAR JOINTING WITH INFILTRATION OF QUARTZ BUT VOID OF MANGANESE

would appear in the first instance, that in the volcanic countries comprising Central America, there exist quantities of manganese; as, for instance, the northern part of the Isthmus of Panama. Possibly volcanism and an extensive circulation of acidic meteoric waters have a direct connection with the formation of manganese deposits. In many of the volcanic rocks of this region manganese is present, mostly combined as a silicate, but probably originally also as an oxide; and it is possible that the groundwater circulation in these tropical countries may act both as a solvent and collector of these manganese compounds.

The effusive rocks are, moreover, ex-

migrate, and the contents leached out." We have, therefore, conditions favorable to a considerable circulation of waters, active in the deposition of ores and their gangues.

SOURCE OF THE MANGANESE

Presumably the presence of the manganese in its present form of oxide is, for the most part, an alteration from its original state as an accessory mineral in the volcanic rocks, in some such form as in the iron, calcium, zinc and manganese silicates. Manganese deposition appears to have many features similar to those of iron; and it is probable that for both, immense as are the propor-

alabandite, is somewhat rare, and, therefore, cannot be accepted as a source of any considerable quantity of manganese deposition. The presence of wad can doubtless be accepted as an alteration, in respect to its physical characteristics, from the harder hydrous oxides, manganese and psilomelane. Neither rhodonite, the silicate, nor rhodochrosite, the carbonate, has been observed, and it would not appear as if rhodonite, the meta-silicate, were the primary form of the manganese.

Passing in brief review we have the following features characterizing this deposit: (1) The entire geological construction of the vein system composed

of effusive rocks, their tuffs and breccias; (2) earth movements with crushing of rock-faces, followed by silicification, forming quartz breccias; (3) a hard blue-green silicified fragmental, that almost invariably accompanies the manganese portion of the lode and its position on the north wall; (4) the presence of an unusually soft manganese filling with vesicular quartz bands comprising the ore of economic importance; (5) masses of red unctuous clay, the resultant decomposition of the feldspars and other soluble silicates, and affording evidence of the easily destructible nature of the basic eruptive rocks; (6) the association of the vein, for the most part, with a sheet of andesite breccia, at times thin, but of varying width, which breccia would appear to have formed (by impregnation and alteration) the larger bodies of ore; (7) the noticeable enlargement of the vein when passing through the soft and porous andesite, and its contraction and impoverishment in the more basic rocks, which from their close texture would not appear favorable to the passage of solutions for any distance into the inclosing walls although the vein itself be sharply defined; (8) and last, when the vein following the softer breccia is inclosed by basaltic rocks, the conditions are not as favorable to the formation of ore as when the breccia is incased by walls of porphyritic texture, usually andesite.

Australasian Mineral Leasing*

By A. C. VEATCH†

The recent mining enactments of all the Australasian states regardless of political complexion, are based on the policy of mineral leasehold. Not only do all the political parties of Australia today heartily indorse this policy, but it represents a gradual evolution from the principle of freehold, through stages varying somewhat in different states.

The mining laws of all these states require continuous development, the enforcement of which is incompatible with the state of freehold. Development as a condition of possession was early recognized in mining practice in the United States; but the annual assessment work required by the present mining law fails to accomplish the continuous development which is requisite to a proper utilization of the mineral resources of the country. On this account the consideration of the extent to which the leasing policy succeeds in securing such development becomes of vital interest.

WESTERN AUSTRALIA

In Western Australia the development of the mineral land laws has been particularly simple. At the time of the first mineral discoveries in 1842, mineral lands were sold under the same conditions as agricultural lands. Later the purchase price was fixed and the option of lease provided. In 1872-73 the erection of a satisfactory mining plant was made a prerequisite to purchase of the land and the rate of lease rent was reduced. Then, after the gold finds of 1885, the abandonment of the principle of sale became a state policy, and in 1898 provision was made that land grants should contain a reservation of all minerals. Thus, in Western Australia the system of leasehold and claim-hold on the conditions of *bona fide* development came at a time most opportune for the test of practice. For the five years comprising 1881-1885 the average annual mineral production was less

ern Australia that 2560 acres is a sufficient maximum for a single holding, except where the coal seam is at a depth of over 1000 ft., in which case 5120 acres is allowed, a decision which is in striking accord with the opinion independently reached in this country and embodied in one of the coal-land bills recently presented in Congress.

The Western Australian mining law is, in short, a wonderfully symmetrical and carefully balanced enactment, and while it may not be, as a whole, applicable to American conditions, it contains many suggestive provisions which merit careful consideration, as they are not the idle vision of some theorist, but the mature enactment of a legislature whose members are chosen entirely by the voters of a great democratic mining state, a state which ranks among the greatest mining countries of the world and which as recently as 1904 has reorganized and revised

^dA considerable area is also held under mining claims, or as prospecting areas.

than £9000, while for the past five years the annual output has exceeded, £8,000,000. Not only was the law subjected to the practical test of great expansion in the mining industry, but an investigation by a commission on mining showed that throughout the goldfields the verdict was overwhelmingly in favor of leasing.

The same general satisfaction with the leasing system is found in the Collie coal-fields, although the coal operations are not comparable with the gold mining. The coal-land law has promoted the development of the industry in this field, which is not so favored by natural conditions as most of the American coal lands. The provisions of this law encourage prospectors by granting exclusive prospecting rights over a considerable area for a limited period, followed by either reward or ordinary leases when discovery has been made. Continuous development is secured by the terms of the lease. The decision was reached in West-

its mining laws to meet the practical work-a-day conditions of a mining region.

The mining law of Western Australia is that of a state in which the mining industry is of preëminent importance. The mineral exports of the country are from five to six times the real value of all other exports. It is, moreover, a mining community in which the capital employed in development is almost wholly of foreign origin. On these accounts the evidence furnished by the development of mining laws in South Australia is to a large degree supplementary to that afforded by Western Australia.

SOUTH AUSTRALIA

South Australia is a country in which mining occupies the subordinate position, the mineral exports amounting to less than one-tenth the value of the other exports, so that the mining law is that of the agricultural holder and local capitalist.

In South Australia the alienation of

*An address delivered before the Conservation Commission, Dec. 3, 1908. Published with the permission of the director of the U. S. Geological Survey.

†Of the U. S. Geological Survey, Washington, D. C.

minerals has been carried further even than in the United States, yet here too, the principle of leasehold has developed and been fully tested. The history of the mining law of this country becomes of special interest to Americans, as it shows the practicability of introducing a system of government leasehold after important mining properties have passed into private ownership.

There has resulted a surprising unanimity of opinion in favor of government leaseholds for all minerals. Mining engineers, operators, and capitalists unite in asserting that mining development is promoted more by leasehold than by freehold. The leaders of the several political parties agree that the matter of government leasehold is not a party question. It is important to note that the mining laws of both Western Australia and South Australia were developed under Conservative or

the United States delayed dealing with the situation the Victorian government attacked the problem at once and by the time of the passage of the American Act of 1866 had evolved a very comprehensive mining law. In Victoria the development of the coal resources has been practically all under government leases notwithstanding the fact that considerable areas of coal land are in private ownership.

TASMANIA

The mining law of Tasmania has been commended in the Australian mining press as the model among the Australian laws from the standpoint of the capitalist. This state was the first to provide that no lease should be forfeited for non-compliance with the development conditions during suspensions of work due to strikes. The last mining act also meets the demands of investors for more secure tenure

there is the same general indorsement of mineral leasehold; indeed it may be said that there is absolutely no demand for private ownership of minerals. The history of government leasing in Australasia and the tenure and conditions under which leases are today issued in the various states are summarized in the accompanying tables.

In the Bennington group of mines at Iron mountain, Shasta county, owned by the Mount Shasta Gold Mining and Milling Company, there has been encountered at a depth of 100 ft. a 6-ft. ledge carrying the same high values as those found on the surface during the last four or five years. A 1600-ft. crosscut tunnel has been run with its mouth on a level with the Iron Mountain railroad, and it is in this tunnel that the ledge has been found.

Tory governments, and while a Labor government has been in power for some years in South Australia, these mining laws cannot be characterized as "radical labor legislation." They are, in fact, non-partisan enactments which antedate the present supremacy of the Labor party.

VICTORIA

In Victoria the national mining law has been enacted under conditions strikingly like those under which the American mining law developed, but with very different results. Here, as in California, there was, at the time of the discovery of gold, no law governing mining on the public lands. In both countries the discovery of valuable goldfields resulted in an enormous immediate influx of population and while

by providing for the expression of the development covenant in money instead of men and by allowing, under certain restrictions, the excess of development expenditure in one year as a credit on the requirements of the next. In Tasmania, at the time of the early discovery of coal under the existing policy of alienation of lands the coal lands passed into private ownership. Yet, today all the working coal mines are reported as operating under government leasehold, showing that the terms of leasing must have proved satisfactory. The present act permits consolidation of leases to any extent in the discretion of the Minister of Mining.

New South Wales is the most important of the Australian states from the standpoint of its coal production. In this state

A strike of gold quartz has been made in the San Carpajaro section above San Simeon landing, on the border line of Monterey and San Luis Obispo counties, Cal., the mine being actually in the former county. A 7-ft. ledge carrying free gold has been found in the old Cruikshank mine which was worked for a time some 20 years ago, but has been abandoned for a long period. The mine is in the Coast Range, and nearly on the coast line, where it was thought gold would not be found. Now high-grade ore has been found at the depth of 50 ft. It is probably another pocket such as was found years ago but the presence of the gold upsets some theories as to the non-existence of gold deposits in the Coast Range of California.

A Model Coal Mine in Westphalia

The Company Works 15 Seams, Varying in Thickness from 1-2 to 10 Ft. Each Bed Is Worked Retreating, and Product Is Carefully Washed

BY WILLIAM S. HALL*

The Zollern II colliery, which is described in this article, is one of the most extensive of several large collieries operated by the Gelsenkirchener Bergwerks-Actien Gesellschaft, and is situated at Merklinde near Gelsenkirchen in Westphalia. The great Westphalian coalfield lies on the west shore of the Rhine. On every side in this region are evidences of great industrial development. Essen with its immense Krupp works is in this district, and at Gelsenkirchen, Dortmund, Bochum, Herne and other large towns are numerous and varied industries with extensive plants. In 1906, 36,000,000 tons of lignite and 130,000,000 tons of bituminous coal were mined in this district. Most of the coal-mining companies are formed into a syndicate which controls about 90 per cent. of the production.

Many of the seams are thin, some are quite dirty, and at places they are highly inclined. One of the first things that strongly impresses an American is the lavish expenditure on the surface plants. The buildings are substantial, fine looking structures, always built of brick or stone, and the machinery equipment is superior. A washery is connected with nearly every colliery and sometimes the entire output goes through the washery. The finest culm coal is saved and is coked, or made into briquets on the premises.

MACHINERY HALL

Fig. 1 is a view at Zollern II, showing the administration building with the offices in the center, with a well kept lawn, trees and flower beds in front and a shaft with a group of mine buildings on each side. Machinery hall is one of the most imposing of the buildings. It is commodious, well lighted, with high ceiling, tiled floor, frescoed walls and stained-glass windows. The floor and machinery are kept scrupulously clean. Aside from its convenient appointments as a central power station, this structure architecturally and in ornamentation is veritably a thing of beauty. The main power plant consists of three triple-expansion horizontal steam engines, directly coupled to direct-connected dynamos. The engines make 90 r.p.m. with 1500 normal h.p. and 1950 maximum h.p., generating a current of 500 volts with 1100 normal kw. and 1450 maximum kw. These machines generate current for the whole plant.

There are two electrically driven air compressors, providing 2300 cu.ft. of air

per min. at 130 lb. pressure. The building also contains the winding engines and other machinery. In a detached building at one end of machinery hall are three banks of Babcock & Wilcox boilers with four boilers in each bank. These are heated by gas from the coke ovens.

HOISTING

There are two shafts similarly equipped and located about 250 ft. apart, as shown by the headframes in Fig. 1. Each headframe is constructed of steel and is given great strength and rigidity. The headframe is supported on heavy concrete foundations and is covered by a sheet-iron bonnet or hood.

The winding engines were built by Siemens & Halske. Each engine is a 350-h.p. machine, and is driven by a direct-

1½ ft. up to 10 ft. in thickness. The beds at Zollern II are moderately flat, the dip varying from 3 to 32 deg. Each bed is worked retreating toward the shaft and the seams are mined in regular order from the surface downward. The work is advanced with such uniformity that all the working faces form an outline that is approximately elliptical.

The method of exploitation varies with the conditions. One method is illustrated in Fig. 2. First the rectangular pillars *aa* are worked out simultaneously. Then the open square spaces are enlarged by working out the parts marked *bb*. Afterward the portions marked *c* and *d* are started, *c* being driven from both ends to meet in the middle. When *c* is well advanced, the next slice *e* is started at both ends. This method is sometimes

FIG. 1. A GENERAL VIEW OF OFFICE BUILDING AND SHAFT HEADFRAMES AT ZOLLERN NO. II MINE

current motor on each side of a 12-ft. steel flywheel weighing 40 tons. Ligier's compensator or equalizer is a feature of the winding mechanism. The Koepe system of hoisting is employed.

The shafts are round, 18 ft. in diameter, 1000 ft. deep, and are walled with bricks. One shaft is used for hoisting and the other ordinarily serves only for ventilation, but is equipped so that it can be employed at any time for hoisting. The cages have four decks, each deck carrying two cars tandem. The flat rope has a cross-section of 288 in. Forty-six men are hoisted in a cage at one time. Hoisting continues for 15 hours each day and the daily output is 2000 tons.

EXPLOITATION

The company operating Zollern II works as many as 15 seams in some of its collieries. These seams vary from

varied by finishing each slice or strip before starting another.

Another method of exploiting the seam is illustrated by Fig. 3. This method is so apparent from the sketch as to require no further explanation. Two men work together in one of the rooms shown in Fig. 3.

Most of the mine timber is creosoted. A gangway timber set is made of two oak legs, each having a wrought-iron strap around the top to prevent splitting, and an iron I-beam for the collar. An iron angle bracket connects the collar with the leg on each side. The main haulage roads, especially near the shaft, are heavily lined with masonry. Side walls are sometimes substituted for the oak legs of the timber sets. Wooden headers are built into the walls so that a certain amount of yielding under the roof pressure may be provided for. Large regular flat stones are used

*Professor of mining in Lafayette College, Easton, Penn.

to face the side walls, while the back is filled in with smaller stones. Wooden partitions are built to retain the culm that is flushed in to fill the worked-out chambers, and these remain in position until the material solidifies. Thus all the open spaces are filled up as soon as possible after they are vacated and the surface is not permitted to settle. In this way mining proceeds under the town without disturbing the buildings on the surface.

Iron props designed to telescope, without injury to the props when the pressure on one exceeds 15 tons, are much used in the rooms. There is but little water in the mine, all of which is drained to one sump in the deepest part and pumped to the surface in one lift.

UNDERGROUND HAULAGE

Three systems of underground haulage are in use; rope, electric and animal haulage. The relative costs of these are as 1, 3 and 9 respectively. Endless-rope haulage and electric locomotives are used on main roads and horses are employed in the secondary haulage. The bodies of the cars are made of sheet iron with curved bottoms. The dimensions of a car are $5\frac{1}{2} \times 2\frac{1}{2} \times 4$ ft., and it holds 8 tons. The car wheels are fixed on the axles, the journals are self oiling and are provided with ball bearings. The wheel base is 18 inches. The rails are unusually heavy for the small light cars. Switches are operated automatically so far as possible, and the air doors are opened by the moving trains and closed by springs or gravity. One endless rope haulage line is over a mile in length.

Each electric locomotive is run by a 4-h.p. storage battery and replaces 30 horses. The locomotive runs at a speed of 13 ft. per sec. hauling 30 loaded cars weighing about three-fourths of a ton each. Each engine has two motors in series or parallel. At the charging station, the locomotive is brought into position between two concrete piers, the tops of which are on the same level as the car platform on which the storage battery rests. In changing the batteries, the battery on the truck is pushed laterally on runners to the pier on one side, and the charged battery from the pier on the other side is substituted.

WASHERY

The washery is of the type in which the coal is classified at the top before being passed through the washery. The plant was installed by Schuchtmann & Kremer, of Dortmund. The cars are run directly from the cage platform into revolving triples and are dumped, the coal passing down over an inclined screen which has a back and forward motion. The over-sizes go to a moving sheet iron picking belt, while the through sizes are elevated to the top of the washery, where they are classified and the different sizes are run to different jigs.

The sizing is done in four trommels

having two divisions with different screen meshes in each trommel. The meshes of the first are 1.5 and 3 in.; second, 0.8 and 1.5 in.; third, 0.4 and 0.8 in.; fourth, 0.15 and 0.4 inches.

The slimes pass into large concrete settling chambers and the water after settling is pumped back and used over again. After the fine coal is drained off until it is sufficiently dry, which requires about 6 hours, it is sent to the coke ovens. The dirt is flushed into the mine. Running water carries the different sizes of coal to storage pockets placed above railroad tracks.

The capacity of the washer is 2000 tons

FIG. 2. A COMMON METHOD OF EXPLOITING THE SEAM

FIG. 3. A GENERAL ROOM-AND-PILLAR SCHEME OF DEVELOPMENT

in 24 hours, 3300 gal. of water per minute are required. The proportion of water to coal is about 1 to 3. There is approximately 10 per cent. of rock in the coal as it comes from the mine. The coke contains from 5 to 6 per cent. of ash. The coke ovens are close to the washery and an improved by-product recovery plant is installed.

VENTILATION

The ventilation is effected by two Rauteau fans. These are electrically driven and give 210,000 cu.ft. of air at 102 r.p.m. Air-test stations are located in various parts of the mine, where the temperature and the amount of air passing are periodically measured and samples of air are taken for gas analysis. The results of these investigations are conspicuously posted at each station. The anemometer

used is a self registering one, and runs for $\frac{1}{4}$ of a minute before beginning to register, and records the amount passed for one minute. The law requires 10 cu.m. (350 cu.ft.) of air per minute for each workman.

When tests show the presence of as much as 1 per cent. of gas in the mine atmosphere, all work is stopped and the miners are taken out. The gangways are sprayed regularly to settle the dust and the timbers are kept wet.

WASH HOUSE

On every side are evidences of the high regard which is paid to the health, safety and comfort of the miners. One of the most interesting and commendable features is the provision made for bathing and change of clothing. The wash house for the employees is one of the largest and most important buildings on the premises. It is well lighted and heated, and has cement floor, tiled walls, and is furnished with a large number of hot and cold water shower baths. Attendants keep the room scrupulously clean.

The miner coming from work goes from the shaft through a covered and heated passageway directly to the wash house. Here he divests himself of all his mine clothing and takes a complete bath, using his individual soap and towel. Then by means of a cord which passes over a small pulley suspended from the roof, he lowers to the floor a complete change of clothing. After putting on his street clothes, he attaches his working clothes to the hook on the end of the cord and hoists them nearly to the high ceiling. The working clothes are dried and disinfected by a current of hot air before he returns to work. When the miner reports for work, he goes to the wash house where he substitutes mine clothes for his street clothing, then he repairs to a near-by lamp room where he is given a certain numbered safety lamp, which has been examined, put in good condition and filled since it was last used. The mine clothes are taken away and washed semi-weekly. All the miners are required to make use of the bath rooms.

LABOR, COSTS, ETC.

The miners work in three shifts of 8 hours each. The night shift is occupied with repair work and with timbering, walling, tracklaying, etc. The miners are paid by the car which holds about half a ton, and receive from 15 to 18¢ per car according to the nature of the work. The best miners make a maximum wage that falls between \$1.50 and \$1.75 per day. The total number of men employed is about two thousand. The miners are given a bonus of 3¢ for every prop that is recovered. The work of filling and prop placing is done by the men without extra pay.

The sanitary arrangements leave little to be desired. Closets for the men are located at convenient places underground.

The closet tanks are removed daily, emptied and disinfected before they are returned.

EQUIPMENT FOR FIGHTING FIRE

A fire-engine house, well equipped with chemical engine, hose reels, hook-and-ladder truck, etc., insure protection against fire. One portion of this building contains a sufficient supply of mine rescue apparatus designed after the Draeger system. One room is used as a temporary hospital and is equipped with ambulance, stretchers and everything that is needed in first-aid to the injured. Gangs of men are regularly drilled in fire fighting and rescue work.

The excellent treatment accorded to us on the occasion of our visit to this mine is deserving of special mention. The company is unusually well prepared to take care of visitors. Before entering, we were supplied with an entire change of clothing, even including underclothes, boots and hat, and were put in charge of a competent and courteous guide. We were given every facility to inspect the plant and all information for which we inquired was freely given. After coming up the shaft, we were conducted to a room in which there were a number of bathing compartments. Each bath room had a tiled floor, porcelain tub, hot and cold water, spray baths, etc. While we were bathing, an attendant brushed our clothes and cleaned our boots.

Pricing Public Coal Lands

SPECIAL CORRESPONDENCE

The United States Geological Survey is placing even greater emphasis this year upon its work of classifying and valuing the public coal lands. The national policy of promoting the most advantageous disposal of the public lands is continued under Secretary Ballinger and by his instructions the Director of the Survey is transmitting to the commissioner of the General Land Office land classifications based upon the reports of findings of the field geologists. To the fullest extent possible under the law the effort is to secure the wisest utilization of the resources of the public domain.

Recently enacted legislation gives to the agricultural entryman whose entry was made prior to the passage of the act, the privilege of electing to take the surface rights, while the coal rights are reserved for future and separate disposition. The chief of the Denver field division of the General Land Office reports that from information received in his office 60 per cent. of the Colorado entrymen in areas supposed to contain coal will elect to take title to the surface reserving to the United States the coal rights. This alone indicates the value and wisdom of this legislation which is the first important amend-

ment of the coal land act along the lines urged by Mr. Ballinger in 1907, when commissioner of the General Land Office.

If the entryman, on the other hand, chooses to contest, then the issue becomes one of relative worth between agricultural and coal values. In a report to Secretary Ballinger, the director of the Survey stated that in the case of the North Dakota lands, to which this act was supposed to be specially applicable, while all western North Dakota, a part of which had been withdrawn as coal lands, is believed by the geologists of the Survey to be actually underlain by workable deposits of lignite, yet in all but 54 townships this area is conceded to be at present more valuable for agricultural purposes than for its deposits of low-grade coal.

The regulations for the classification and valuation of the Government coal lands as revised in April provide for a somewhat more discriminating separation of the coal and the barren lands, and for the fixing of more adequate valuations upon lands underlain by the higher grades of coal. These changes were determined upon by the Secretary of the Interior from the consideration of present conditions in coal mining in the Western States, where thinner and deeper beds are being mined than was formerly the case, and of current practice in the matter of coal royalties collected both by the States and by private land owners. Two of the regulations indicate the spirit of these administrative measures for safeguarding the disposal of the nation's remaining coal lands. The price of coal land containing the lowest grade bituminous coal or lignites is fixed at the minimum provided by law, the intent being to thus encourage, as far as the law permits, the immediate utilization of these low-grade fuels. Another rule states that in all valuations of coal beds, any special condition enhancing the value of the land for coal-mining purposes shall be taken into consideration.

The revised scheme used in the valuation of the coal lands differs from that formerly in force in two general respects. The basis is now specifically that of coal tonnage and the land prices thus determined for the better grades of coal, anthracite and coking bituminous are somewhat higher, the maximum being raised from \$100 to \$300 per acre, and indeed this maximum does not hold in "districts which contain large coal mines where the character and extent of the coal deposits are well known to the purchaser."

SCHEME FOR VALUATION OF COAL LANDS

The plan of valuing the public coal lands by accurate determination of coal quality and tonnage is the most equitable possible, and while adequate returns are secured to the Government, the land prices thus fixed rarely amount to one-fourth of the results prevailing in the same districts where private interests.

The present scheme of valuation is as follows: Anthracite and coking-bituminous coals are valued at 2 to 3c. per ton. High-grade noncoking bituminous coals are valued at 1 to 2c. per ton. High-grade subbituminous and low-grade bituminous coals are valued at $\frac{1}{2}$ to 1c. per ton. Low-grade subbituminous coals and lignites are valued at the minimum price fixed by law of \$10 and \$20 an acre. The tonnage is conservatively estimated and actual recovery ought always to exceed the tonnage upon which the valuation is based.

A few instances are cited as showing the comparative working out of valuations under the different land policies. In one township near Rock Springs, Wyoming, the valuation of which has just been completed by the Geological Survey, the coal-land values aggregate \$2,800,000, on the basis of 1c. per ton. The amount for which the Government would have sold these lands on the basis of the minimum price allowed by law under the interpretation which held prior to 1906, is \$460,000, while under the valuation plan of last year the amount would have been a little less than \$1,000,000.

In a Montana township, near the town of Roundup, on the new line of Milwaukee, the original amount which the Government would have received under the \$20 minimum rate was \$112,000; under the regulations of last year, \$141,000; and under the present valuation scheme adopted April 21, by this administration, \$370,000, some of the coal being now valued at \$65 an acre where \$20 and \$25, respectively, would have been the former rates.

Near the great Castlegate coalfield in Utah the Survey is now valuing some of the Government land containing thick beds of coking coal. In this field, thousands of acres would run over the maximum of \$300 an acre, as opposed to the \$20 minimum price and \$75 under the former valuation scheme. Dozens of other equally striking instances of comparative valuations might be cited.

GOVERNMENT RECOVERS COAL LANDS

The conservatism of even the present valuation plan is clearly shown from an examination of the records in several cases where land was fraudulently entered by certain companies and in which suit for recovery of land and damages was instituted by the Government. In one instance of this kind a coal company secured a tract of land through fraudulent entries—paying \$20 an acre, however—and instituted mining operations. The company has settled by paying the Government 8c. per ton royalty for all the coal mined and would have gladly accepted the privilege of being allowed to continue the mining at this rate. This, however, was not possible under the law. In this case the Government received the original \$20 an acre, as well as \$31,000

in royalty for the partial working of the coal on the 74 acres involved, and has also got back the land. Had the company been permitted to mine out the coal, including that left as pillars, the return to the Government would have been \$1320 an acre. Under the present scheme of valuation this land would have been sold at \$340 an acre.

Not only are the prices determined on the basis of the present plan believed to be not excessive, but a higher valuation would have been very properly approved by Secretary Ballinger were it not for the fact that the coal-land law limits the coal land that may be acquired to an acreage below what a mining company needs for economical operation. It is evident that a purchaser could well afford to pay a larger price per acre did the law permit the purchase of the larger tract.

It will be seen that the present coal-land policy provides for the saving to the Government and the people of enormous sums of money and prevents the monopolization by private interests of the western coalfields. The most advanced, scientific and effective methods of classifying and valuing the nation's remaining coal lands, which still constitute about 80,000,000 acres, have been adopted, and in brief the intent of the policy developed by Secretary Garfield and now further advanced by Secretary Ballinger is to promote development and economical utilization and at the same time to secure adequate returns from these valuable public lands.

Ohio and West Virginia Coal Railroads

SPECIAL CORRESPONDENCE

In a report sent to Congress May 10, the Interstate Commerce Commission has given the results of an investigation just completed with regard to certain coal roads in Ohio and West Virginia and designed to reveal their position under the "commodities clause" of the Hepburn act.

In this report the Commission presents a comprehensive history of the organization and operation of various coal companies in Ohio and West Virginia and their merging into one company which is controlled by a syndicate of railroad companies. The various coal companies considered are the Hocking Valley Railway Company, the Toledo & Ohio Central Railway Company, the Kanawha & Michigan Railway Company, the Zanesville & Western Railway Company, the Buckeye Coal and Railway Company, the Ohio Land and Railway Company, the Central States Construction Company, the Sunday Creek Coal Company, the Rayhould Coal Company, the Boston Coal Dock and Wharf Company, the Kanawha &

Hocking Coal and Coke Company, the Continental Coal Company, the Sunday Creek Company, the Wheeling & Lake Erie Railroad Company, and what is known as the "Trunk Line Syndicate." This Trunk Line Syndicate consists of the Pennsylvania, the Baltimore & Ohio, and the New York Central systems, as well as the Hocking Valley, the Toledo & Ohio Central, the Zanesville & Western, the Kanawha & Michigan, the Wheeling & Lake Erie, the Chesapeake & Ohio, and the Norfolk & Western roads.

A great part of the report is taken up with a minute description of the manner in which the various coal companies and railway companies in this region were finally merged into the Sunday Creek Company, which was incorporated under the laws of New Jersey. In the history of these financial transactions the Commission goes into great detail as to the issue of stock and bonds and the giving of bonuses to various organizations accomplishing the mergers.

The report farther states that the Trunk Line Syndicate considered and passed upon track connections, operation of coal properties, reorganization of coal companies, merging of coal companies, and in general exercised supervision over such matters; also that the Trunk Line Syndicate was prominent in the policy of the roads in this district in refusing to make track connections at mines with other properties than those dominated by the syndicate.

The Commission considers that present conditions have resulted from the foregoing manipulations, and one of them seems to be the policy of the Hocking Valley and the Kanawha & Michigan railways to discourage all further development of coal mines tributary to their lines by refusal to make track connections and by imposing burdens upon the operators when the connections were conceded.

The evidence shows that in the period from 1902 to 1905 a large number of requests were made upon the Hocking Valley Railway Company by coal companies for track connections, which were not considered favorably by the railway company and in most of which the efforts of the coal companies failed.

The assistant to the president of the Hocking Valley railway could not name any other mines than the Johnson Coal Mining Company, the New York Coal Company, and the Sugar Creek mines at which connections had been made between 1900 and 1907, although it is stated that during this period there were 18 requests for connections. A similar condition of affairs appears as to the Kanawha & Michigan Railway Company in regard to refusing track connections and furnishing of cars.

It seemed to the Commission that after the organizations and mergers above described, the railway companies by various

devices sought to discourage the further development of coal mines in the territory under discussion. The interest of the railroad officials in their coal companies and the guaranty by the railways of the bonds of the coal companies furnished an incentive to discourage further development of coal mines, and as far as possible to retain to these coal companies a monopoly of the coal transported by these railroads.

Coal Mining in Georgia in 1908*

The total production of coal in Georgia in 1908 was 264,822 short tons, having a spot value of \$364,279.

Few States suffered more acutely from the financial depression of 1908, so far as coal production is concerned, than Georgia, the output of the State decreasing from 362,401 short tons in 1907 to 264,822 tons in 1908, a decline of 97,579 short tons, or 26.93 per cent, while the value fell off from \$499,686 to \$364,279, a decrease of \$135,407, or 27.1 per cent. The output in 1908 was less than in any year since 1899 and can be attributed almost entirely to the depression in the iron trade, which particularly affected the production of high-grade coals and the manufacture of coke. The quantity of coal made into coke decreased from 141,031 short tons in 1907 to 71,452 tons in 1908—almost exactly 50 per cent. Of the total decrease in the State's coal production in 1908, 71 per cent. was in the quantity of coal charged into ovens for the manufacture of coke.

The number of men employed in the coal mines of Georgia in 1908 was 970, who worked an average of 201 days, compared with 808 men for an average of 262 days in 1907 and 737 men for 279 days in 1906. The efficiency record of the laborers in the coal mines of Georgia can not properly be compared with that of other States, however, as a great number—considerably more than half—are convicts leased by the State to the mining companies. Most of the men worked nine hours a day, but the statistics of production show that the average output per man each day during 1908 was only 1.51 tons, compared with 1.71 in 1907 and 1.62 in 1906. The average production per man for the year was 305 tons, compared with 449 tons in 1907 and 450.6 tons in 1906. This low efficiency is explained by the fact that the convicts employed in the mines have had no previous experience as coal miners. Where convicts are employed the operations are not subject to interference by labor troubles. There are no undercutting machines in use in the mines of Georgia. At one plant washing machinery is employed, and in 1908, 70,000 tons of coal were washed, yielding 71,452 tons of cleaned coal and 7548 tons of refuse.

NOTE.—Table is based on one cubic foot of water, weighing 62.4 pounds. A column of water 1 inch in depth and 1 square foot in area equals 5.2 pounds.

The accompanying table of water gages was compiled and copyrighted by Charles Kuderer, of Woodlawn, Penn. It is based on actual tests made on a centrifugal mine-tan wheel, 3 ft. wide, 6 ft. in diameter, and with 2 inlets of 3 ft. diameter. The fan wheel was inclosed in a casing, the air flowing from this casing into the atmosphere; the pressure in the fan casing and the corresponding air velocity were taken.

Tin Deposits of the Carolinas

BY S. MAYS BALL*

Tin is supposed as having been discovered in North Carolina near Kings Mountain in 1883. It was not until 1886, however, that systematic prospecting was carried on in this vicinity. In 1888 a to-stamp mill was erected by Mr. Ledoux and associates for test purposes, but owing to litigation, work on the property ceased in the latter part of 1899. A little work was done on the Chestnut Hill property about 1892. Since that time, little or no work was done on the tin belt until 1903, when the Ross mine, at Gaffney, S. C., was discovered. The principal developments to date are the Ross mine, at Gaffney, S. C.; the deposits in the vicinity of the town of Kings Mountain, N. C.; on the southern end of Chestnut Ridge, about 2½ miles northeast of Kings Mountain; and on the plantation of John E. Jones, 7 miles northeast of Kings Mountain.

THE ROSS MINE

The principal development of the tin belt has been done at the Ross mine, situated about one mile easterly from Gaffney, S. C. Near the top of a low hill, beside which flows a small stream, a shaft was sunk and an open cut made; in these were found saprolitic-pegmatitic dikes, carrying varying amounts of tin ore. Just above this shaft and pit another shaft 40 ft. deep was sunk. Trenches were cut across the supposed strike of the veins, but only a small amount of tin was obtained. Numerous pits and trenches in the vicinity showed from 12 to as high as 75 lb. of tin ore to the cubic yard. The average for the soil and gravel is about 25 lb. per cubic yard.

A 40-ft. trench run back from the stream showed some good ore in the sand and gravel overlying bed rock. The area over which cassiterite has been found in the soil and gravel is about 1000x600 ft.; all of this material will undoubtedly pay to wash.

OTHER TIN DEPOSITS

Tin ore is found at a point about three

*Atlanta, Ga.

miles above Grover, N. C.; a distance of about 13 miles from the Ross mine. From this point it has been found almost continuously to points a mile or two above Lincolnton, N. C.; a total distance of about 28 miles. However, the principal deposits are at a distance of 7 miles northeast and southwest of Kings Mountain.

The Ledoux property is situated about 4½ miles southeasterly from Kings Mountain. This was worked extensively some years ago by trenches and a shaft, but is now idle. Tin ore has been found at various points on the plantation of E. C. Faires, and also on the Weir plantation, just southwest of Kings Mountain. Northeast of the Faires plantation some work has been done on the Falls property. A number of shafts were sunk and trenches cut and some rich ore encountered, but it was found to be pockety. Cassiterite, in the form of small pieces from the size of a grain of sand to that of a pea, has been found in small quantities at various other points in this vicinity.

About two miles northeast of Kings Mountain, toward the southern end of Chestnut Ridge, on the property of M. M. Carpenter, tin-bearing boulders weighing from 50 to 100 lb. each have been found. A little to the east of the summit of Chestnut Ridge, about ½ mile from the Carpenter property, a shaft was sunk 122 ft. on a tin-bearing vein. This is reported to be 7 ft. wide at 100 ft. depth, and is said to carry 3 per cent. tin oxide. Judging from the dump, there was not a great deal of tin ore removed from the shaft. It is reported that ore was encountered in a trench on the Ormond property, on the north end of Chestnut Ridge. On the Hovis property, about 2 miles from the Ormond property, little tin has been encountered, but the ground adjoining it on the north again shows prominent tin-bearing boulders.

The Ramsaur Mill property lies about 1/3 mile northeast of the Ormond; here a large pegmatitic dike outcrops, and a great deal of cassiterite has been found as float. A trench on this ground also exposed rock carrying cassiterite. One of the most promising deposits is found at the Jones mine, about 7 miles northeast of Kings Mountain and 3½ miles northeast of Bessemer. A number of shafts were sunk here, but they have since partly filled with waste, etc.

PRODUCTION OF TIN FROM THE CAROLINAS

The first production of tin from the Carolinas was made in 1903, when the Ross mine shipped 38,471 lb. of tin concentrate to England for treatment. The Jones mine also produced some ore during development work, but none was shipped. No shipments were made during 1904, but development work was actively carried on by the Carolina Tin Company at the Jones mine. The Beaver Dam property, 11

miles northeast of Kings Mountain, was also worked in 1904. There was no production in 1905, although prospecting and development were actively carried on in the Kings Mountain district. At the old Ledoux mine, a mill was erected to handle, not only the Ledoux ores, but those from other neighboring properties. During 1905, a small mill was erected at the Jones mine; a small amount of ore was treated, but none was shipped. The property was worked to a depth of 100 ft. and some very good ore was exposed. Perhaps the most extensive development in 1905 was on the property of the Piedmont Tin Mining Company, beginning 2 miles southwest of Lincolnton. The property is about 2 miles long and 1 mile wide and has been prospected almost over its entire area. The greatest amount of underground work was done at the Main and Henry shafts.

In discussing the work in the Carolina tin belt for 1905, Dr. Joseph Hyde Pratt, geologist of North Carolina, states that although a comparatively large amount of work had been done, it had not yet proved conclusively the real value of the tin belt. The work demonstrated, however, that economical and careful management will be necessary to make the deposits profitable.

Much development work was done in North Carolina during 1906 and 1907, but no ore was shipped or sold. The Piedmont Tin Mining Company began the erection of a mill to treat its own ore. Present conditions are about the same as those of 1906 and 1907.

Cadmium in Soft Solders

While ordinary solder answers well for many kinds of work, in others its melting point is not sufficiently low. Erwin S. Sperry (*Brass World*, May, 1909) states that the mixture of about two parts of tin and one part of lead has the lowest melting point of any of the tin and lead mixtures, so that it is impossible with tin and lead alone to obtain a more fusible solder than this one. It is not generally known that the addition of cadmium to soft solder containing tin and lead greatly improves it by lowering its melting point and increasing its strength. Now that cadmium can be obtained at a reasonable price, its use in making a soft solder with a low melting point should become extensive.

The best mixture for the soft solder containing cadmium has been found to be the following: tin, 50 per cent. (2 parts); lead, 25 per cent. (1 part); cadmium, 25 per cent. (1 part). The metals are melted together and a small quantity of sal-ammoniac is used on the surface as a flux. This cleans it well. Before pouring into bars, the solder should be well stirred in order to thoroughly mix the metals. When

cast, the bars of this solder have a slight roughness on the surface caused by crystallization, but this does not detract from their value. The cadmium increases the strength of the solder as can be easily ascertained by bending the bar. The stiffness will usually surprise those who are accustomed to use ordinary soft solder.

The melting point of this cadmium solder was carefully tested by means of an accurate thermometer and found to be 202.1 deg. F. (144.5 deg. C.). This is about 30 deg. lower than the best solder composed of two parts of tin and one part of lead.

As cadmium is now not very expensive, the cost of the solder is not increased very much. It will be found useful for soldering soft metals such as britannia, pewter, antimonial lead and similar metals of a low melting point, and will tend to render the soldering operation much safer, as there is less danger of melting the metal to be soldered.

Roasting Furnace

Francis D. Weeks, of Salida, Colo., describes (U. S. Pat. 916,903, March 30,

The Engineering & Mining Journal, N.Y.
WEEKS ROASTING FURNACE

1909) an apparatus for calcining, agglomerating and sintering ores. As applied to a circular furnace, the apparatus is illustrated in the accompanying engraving showing a top plan view, partly sectional. The ore is put into a hopper mounted on the revolving frame and fed automatically to a stationary perforated grate below. The frame revolves slowly enough to permit an oil or gas burner at one side of the hopper opening to ignite the ore as it is discharged and air drawn or forced through the ore completes the combustion. When the frame has completed a revolution, that portion of the ore first ignited has become sufficiently calcined or sintered and is ready to be discharged from the grate surface by the scrapers attached to the revolving frame. The ore to be treated is not moved from the time it is deposited on the grate until discharged into the bins around the peri-

phery of the furnace. While a circular furnace is shown in the accompanying engraving, the apparatus may be applied to a straight-line furnace.

Conditions in Nicaragua

Judging from the reports of miners and others returning from Nicaragua, that country offers little or no inducement to the miner seeking employment. The majority of the mines employ negroes and natives almost exclusively, even on their staffs, because of the low cost for this class of labor. The few mines that prefer white men are overrun with applicants for work. It is reported that many efficient miners, unable to secure employment, have found it necessary to apply to charity for funds with which to leave the country. Prospector, unless plentifully supplied with money, fare even worse than the miners. Local assistance is practically impossible to secure, and as living expenses are very high, the prospector out of funds faces a serious problem. Some of the more unfortunate have found it necessary to walk out of the country on the beach over to Costa Rica or Honduras, feeding on coconuts and crabs during their tiresome journey.

It seems that there are on the Atlantic coast of Nicaragua promising deposits of various minerals, but without the aid of foreign capital, there is little hope for their development. The excessive import duties on provisions and export duties on gold have in a large measure retarded the investment of foreign capital. Mining concessions, moreover, are very questionable under all circumstances. Not only are mineral concessions contrary to the constitution, but all of them contain loopholes so that they can be annulled under some pretext or other. Mineral concessions are often obtained by parties who have not the slightest intention of working the properties, but who plan to pass them off on the uninformed foreigner for whatever they can get.

Mines which have been acquired under the mining code are, of course, fully protected, and such mines may be made to yield a fair profit by judicious management. Good prospects are numerous, but the money to work them must come from the outside.

In Russia there are several salt lakes and rock salt deposits in the Caucasus. According to consular reports, the more important ones belong to the state and are situated principally in the governments of Erivan, Baku and Stavropol, and in the provinces of Kars, Daghestan and Ter. Their annual output is estimated at about 1,500,000 poods (24,100 tons). All salt produced in the Caucasus is either locally consumed or sent to Central Asia markets; none of it is exported.

The Determination of Tungstic Acid in Low-grade Ores

The determination of small quantities of tungstic acid by known methods is difficult, and involves much time and labor. In a paper by H. W. Hutchin and F. J. Tonks (*Inst. Min. and Met., Bull. No. 56, May 13, 1909*), the three methods of analysis in common use are described; in addition, a new scheme, more speedy and accurate, is investigated. Following are the methods of analysis in common use: (1) The aqua regia method; (2) aqua regia method with previous treatment with hydrofluoric acid; (3) fusion with alkalis and subsequent determination with mercurous nitrate.

AQUA REGIA METHOD

Five grams of the finely powdered sample are digested at the boiling point with 50 c.c. of hydrochloric acid for several hours; 10 c.c. nitric acid are then added and the digestion continued for one or two hours. The assay is well diluted with water and allowed to stand over night. After filtering and washing, the tungstic acid in the residue is dissolved in dilute ammonia, filtered and the ammonium-tungstate solution evaporated in a platinum dish. The tungstic acid obtained from ignition of the ammonium tungstate is evaporated with hydrofluoric acid to remove silica, and again ignited.

AQUA REGIA METHOD WITH PREVIOUS TREATMENT WITH HYDROFLUORIC ACID

Five-gram charges are evaporated with hydrofluoric acid in a platinum dish to dryness. The dried residue is subsequently transferred to a beaker with water, giving a volume of about 40 c.c.; 5 c.c. nitric acid are added and the assay gently warmed to remove the bulk of the mispickel. After diluting well and allowing to stand over night, it is filtered and the residue washed on to the paper, dried and burned. The residue, after powdering again in an agate mortar, is decomposed by aqua regia, etc., as previously described.

DETERMINATION BY FUSION WITH ALKALIS AND SUBSEQUENT DETERMINATION WITH MERCUROUS NITRATE

The silica and mispickel are removed from a 5-gram charge as described in the previous method. The residue is again powdered and fused in a nickel dish with caustic soda and sodium peroxide. The melt, when cold, is extracted with water and diluted to 250 c.c., of which 200 c.c. of a filtered proportion is used for the actual assay. The alkaline liquor is acidulated with nitric acid, followed by ammonia, till fairly alkaline, boiled, filtered and washed. The filtrate containing the tungsten is made neutral or faint-

ly acid with nitric acid; mercurous nitrate solution is then added, followed by a little freshly precipitated HgO or a few drops of diluted ammonia. After warming and stirring, the precipitate settles well. It is determined as WO_3 by ignition in a platinum crucible, followed by treatment with hydrofluoric acid.

NEW METHOD

That wolfram is decomposed by boiling or by digestion on a water bath with caustic soda solution, was noted in the course of laboratory experiments on wolfram products. Investigations followed to see if the reaction could be adapted to replace the fusion with soda. With a view to its use as a solvent for wolfram in low-grade ores it was desirable first to test it on wolfram concentrate. A sample of wolfram concentrate was selected which had been agreed upon by buyer and seller; it contained 63.2 WO_3 .

The finely powdered sample (0.4146 gram, was digested on a water bath with about $1\frac{1}{2}$ -inch stick soda and 15 c.c. of water in a porcelain dish for 45 min. The assay was diluted with water, a little sodium peroxide added, filtered and washed. The tungstic acid was determined in the filtrate by mercurous nitrate after removal of silica, etc., as in previous methods. The weight of WO_3 obtained was 0.2610 gram = 62.97 per cent. WO_3 . The decomposition of wolfram under such conditions was sufficiently complete to make possible the assay of low percentages.

DETAILS OF NEW METHOD AS USED FOR LOW-GRADE ORES, TAILINGS, ETC.

The charge taken may be 5 grams or more; it is better, however, to use 3.6, 11.2, 16.8, or any convenient multiple of 2.8, so that the milligrams of tungstic acid obtained represent simple ratios of pounds of WO_3 per long ton of ore. The reason for taking 2.8 grams (or multiple) is because only four-fifths of the solution is used for the actual assay, i.e., it is a convenient sort of assay ton for pounds per ton of 2240 lb. under the special conditions of the assay. The charge is digested in a 4-in. porcelain dish with 20 c.c. of a 25-per cent. solution of caustic soda (free from chloride) on a water bath for 30 to 45 min. The assay is next diluted, a little sodium peroxide added to oxidize any decomposition products of sulphides, then transferred to a $\frac{1}{2}$ -liter flask and diluted to 250 c.c.; 200 c.c. of a filtered portion are first acidified with nitric acid, then made alkaline with ammonia. The assay is brought to the boiling point, filtered and washed. The filtrate is made slightly acid with dilute nitric acid and mercurous nitrate solution added in excess, followed by a few drops of dilute ammonia. On warming and stirring the precipitate settles readily.

After filtering and washing the precipitate with weak mercurous nitrate solution, the paper and precipitate are ignited together in a porcelain crucible; or, if the ore is free from arsenic, in a platinum crucible. Weigh as tungstic acid; with a charge of 5.6 grams, the milligrams obtained, divided by 2, give pounds of WO_3 per ton.

For assays of ores and tailings, the sample may be reduced to a sufficient degree of fineness in a wedgwood mortar, but for concentrates an agate mortar is necessary; fine powdering is essential. For decomposing charges containing not more than 0.4 gram of tungstic acid, 20 c.c. of a 25-per cent. solution of caustic soda is sufficient. The attack with soda is rapid under these conditions, 0.4 gram of wolfram concentrates being decomposed in 15 min. to the extent of 98 per cent. of its tungsten content. As a rule, however, from 30 to 45 min. is given.

STRENGTH OF MERCUROUS NITRATE SOLUTION

The solution may be conveniently prepared from mercury. From 2 to 3 oz. of mercury is digested on a hot plate for $1\frac{1}{2}$ hours in a large beaker or flask (the hot plate being near the boiling point) with 25 c.c. of nitric acid (specific gravity 1.4) and 75 c.c. of water, and left on the hot plate over night. The extract, diluted to about 400 c.c., will give a saturated solution with the minimum of free acid; 20 c.c. is sufficient for most assays.

Where a porcelain crucible has (from the presence of arsenic in the ore) necessarily to be used, it is advisable to burn a batch of precipitates one after the other, and at the end transfer the accumulated tungstic acid to a platinum crucible for treatment with hydrofluoric acid. The loss of hydrofluoric acid is usually very small, e.g., on three assays of mineral from the battery, working with a charge of 5.6 grams, the total loss was 0.5 mg., equivalent to 0.08 lb. per ton on each assay. In the presence of scheelite, the method is not applicable, since the mineral is only partly attacked under the conditions of the assay.

According to the *Aust. Min. Stand.* April 7, 1909, several discoveries of diamonds in Australia have been recorded. Some of them, notably those in the neighborhood of Bingera, Cope's creek and Inverell, have demonstrated the existence of the gems in fair number, but mostly of small size.

Statistics collected for THE MINERAL INDUSTRY show that the production of cadmium in the United States in 1908 was 10,000 lb., valued at \$2,300. This was the second year that cadmium was produced in the country, 15,000 lb., valued at \$18,750, being produced in 1907.

Rules for Smokeless Consumption of Fuel

BY ROBERT GRIMSHAW*

That the smokeless consumption of fuel by others than ourselves is a desirable end to attain, we are all ready to admit; but as a rule, we consider it to be an altruistic ideal which we cannot afford to entertain. There are times, however, when the law steps in and calls for it; and then we suddenly find that it is attended with fuel economy. The trouble is, how to attain it. The "*Magdeburger Verein für Dampfkesselbetrieb*" or "Association for Boiler Running," has laid down several rules by which the result may be attained; and the first four conditions are as follows:

1. During combustion there must be sufficient air supply.
2. The air and the combustion gases require constant intimate mixture.
3. In the fire-chamber it is necessary that all shall be red-hot, in order to ignite the incompletely consumed combustion gases.
4. Very solid fuel requires time for its complete combustion.

The permanent fulfilling of these conditions is certainly attended with a series of difficulties. The main trouble lies with the constant change of all the conditions and processes connected with combustion. For instance, the varying call for heat, caused by the fluctuating demand for steam, the varying size of the mass of coal on the grate, the intermittent addition of new coal thereon, the coking of the coal layer, the gradual collection of cinders and slack on the grate—all aid in effecting a constant change in the conditions of combustion, and increase the difficulty of maintaining the conditions constant. Farther, every kind of coal has different qualities from all the others. It is then not sufficient that the stoker shall know the proper conditions for perfect combustion; he must be careful and have practice, in order to combat the difficulties which confront him.

THE LAYER OF COAL MUST NOT BE TOO THICK

In order that the proper amount of air shall always be present, the layer of coal on the grate must be kept loose and penetrable; that is, it must not be too thick. The proper thickness has to be learned by experience; so that with the greatest amount of draft, all the air that passes through shall be consumed. Naturally, coal which lies loosely on the grate may be carried thicker than that which by reason of its size and shape packs closely. The smaller the coal, the thinner the layer may be. The pieces should not be larger than one's fist; larger ones must be broken up; those the size of a potato being the

best. With medium draft, the layer can be about 4 in. high. Pea and buckwheat coal should be fired only about 2 in. high or even less.

Whatever is the best thickness of layer on the grate, the stoker should keep it regular. He should not let the fuel burn too long without adding fresh coal. "Little and often" should be the rule. In firing, the layer should be kept as level as possible, that is, the thin places should receive special attention, so as to keep the layer level. I also believe that the fire should always be a trifle higher along the edges of the fire-chamber than in the center; there are apt to be leaks, and any draft in this circumferential line tends to cool down the walls, which should be kept glowing. Every locomotive fireman sees this without being told. The glow under the freshly laid coal should not be smothered; it must radiate through the new material into the combustion chamber; the flames should at once, on the fire-door being closed, break out anew and light the gases evolved from the latter. The fresh coal is to be strewn over the entire surface; not shoveled in, as into a wheelbarrow. Fresh coal is to be added as soon as the flame on the grate is thin and short, and before the glow is checked.

If enough air cannot be got through the grate to burn the gases evolved from the new coal, sufficient must be admitted through the partly open fire door to effect this; but only as long as these gases are evolved. The proper time can be determined by experiment.

Coking coal must be sliced before firing anew; otherwise it will not allow sufficient air to pass through it. This slicing often causes a greater development of gas than fresh firing; so that after slicing, air should generally be let in above the grate.

In order to mix the air as thoroughly as possible with the combustion gases, it is well to have a contracted space back of the fire-chamber. The size and shape of this space are best determined by experience, each case for itself.

The strength of the draft is not to be judged by the smoke, but measured by a manometer. If considerable air over the grate is desirable, and only a small amount of draft is necessary for the steam demand, it may be best to blow in the air above the fire; but for simplicity's sake this is, as far as possible, to be avoided.

CONTROL OF THE FIRE

Control of the condition of the fire is afforded by the flame. When seen from behind, it should not be short and broken, nor should it wave like a flag in the wind. This latter would be the sign of too thin a layer of coal on the grate. Under such conditions the flame is perfectly white, and the chimney does not smoke; but outside of the case of very "thin" coal, that is, that which is not "fat," the proper flame should be long, say 2 to 4 in.; must fill the entire flue passages, and roll and

wave like a fiery sea. Such a flame is not perfectly white, but red or yellow. In any case it is bright, and the chimney will smoke but little, with a very gray smoke.

If the flame is dark, black and long, the stack will smoke plentifully; this is caused by lack of air or heat or both together in the fire-chamber.

The layer of coal should be disturbed as little as possible; it should be lessened only if it cokes or cakes. In such cases, one should be careful to let the ashes and cinder lie as far as possible untouched on the grate, and not let them get mixed with the coal; otherwise they will melt, cover the coal with a coating, and prevent its combustion. It is best that the cinder should not melt on the grate, but lie thereon as a dry, loose, porous mass. As soon as the ashes restrict the room in the fire-chamber, or the supply of air through the grate, they must be drawn off. It is advisable to have the upper edges of the grate bars slightly grooved, so that there will always be on each one a slight protecting layer of ash which will prevent them burning.

If the damper is always open, and after the admission of air above the grate there is not enough steam, that is a sign that the plant is overworked, and that smokeless combustion is impossible.

The above rules are especially adapted for stepped grates, and "half anthracite" coal.

An interesting experiment was made recently at the Garswood Hall colliery in Scotland. The screens at this colliery are near the downcast shaft, and a considerable quantity of dust is made in the process of screening, some of which finds its way back into the mine along with the ventilation. To obviate this, water-sprays have been fitted up at the bottom of the shaft, and also a frame has been put in the main airway a little distance from the shaft. Arranged around this frame are several sprays, the object of which is to wash the dust from the air as it passes through the frame. Quite a considerable amount of dust is thus washed out. With 40,000 cu.ft. of air passing through, $7\frac{1}{2}$ lb. (weight after drying) of dried dust were recovered by means of a settling-tank in 14 hours, and probably as much more escaped collection, which means that the sprays washed down 14 or 15 lb. in the 14 hours. This dust originated partly at the screens and partly from the trams in the pit-shaft.

In the Usher sand process the pulp is run directly from the mill into the treatment tank where, as the tank fills, it is claimed that the slimes are completely separated and run to the slimes plant, leaving only clean sands in the vat, and after a short time only for draining, the treatment is started without the delay and cost of transfer.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Prop. and Treas. ROBERT MCKEAN, Sec'y.
365 Pearl St., New York.
London Office: 6 Boulevard Street, London, E. C., Eng.
CABLE ADDRESS: "HSCMINJOUR, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings, 33 marks, or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for May, 1909, was 52,000 copies.

June 5..... 11,000

None sent free regularly, no back numbers. Figures are live, net circulation.

The Economics of Natural Gas Supply

Even at the present time there is a great deal of misapprehension respecting the value of a supply of natural gas. It is now well recognized that in no case is the supply inexhaustible, but on the contrary, with respect to any particular reservoir it is likely to be of short duration. Also it is now recognized that natural gas is not a costless fuel, although those who in the early days of some fields were able to obtain four or five million cubic feet per day from a single well (costing about \$1500), connected with the factory by perhaps 2000 ft. of 4-in. pipe line, obtained a supply of fuel at very low cost indeed. In some cases, it was possible to obtain a gas well within the yard of the works. Such favorable conditions, however, no longer exist; or if they do, the instances are extremely rare.

A supply of natural gas involves expense under the following heads: (1) Acquisition of property and the right to drill for gas, either by purchase of the fee or by lease. (2) Drilling and equipping the wells, cost of which varies with the depth to which drilling must extend, and also with the percentage of dry holes. (3) Connection of the wells by pipe lines to the place where the gas is to be used, ordinary industrial piping being frequently from five to eight miles in length, the size of the pipe being commonly 4, 6 or 8 in. (seldom as small as 4 in. for a line of such lengths). (4) Care of wells, pipe lines and other equipment, an ordinary industrial supply usually requiring the continuous attention of a fieldman. (5) Prospecting and development, in order to extend the supply to take the place of that which is exhausted.

The gas lands of an industrial company, which furnish its fuel supply, are analogous to coal mines, and they should be considered as an independent mining department. Otherwise, the real cost of the fuel is likely to be overlooked. Gas mines differ from coal mines in that their product is not confined, and that other persons may secure it, unless the territory controls the entire area of a pool, which it is rarely possible to accomplish. In brief, gas lands merely confer the right to take gas from a common reservoir.

Natural gas occurs in nature in strata

of sandstone lying at various depths below the surface. The original rock pressure appears to be more or less in proportion to the depth below the surface, being the higher the greater the depth. In order to retain an accumulation of gas, the sandstone must be covered by a stratum of some impermeable rock. The precise manner in which the natural gas occurs in the sandstone is unknown; but whether the original occurrence be as a gas or as a liquid saturating the porous sandstone, it is found that the existence of the gas is confined to certain circumscribed areas, which may be pictured as subterranean lakes, or pools, as they are commonly called. The existence of a pool having been determined, a well drilled anywhere within its boundary is likely to find gas; but not necessarily, inasmuch as it may go down in a barren spot, which may be conceived to be an island in the pool. As illustrative of the dimensions of a gas pool, the well-known Iola pool in Kansas may be cited. This was about 10 miles long and about three miles wide, and is perhaps the largest single pool yet found in Kansas. We have had occasion to study other pools, but none of which the dimensions were so great or the uniformity of the gas occurrence so striking as at Iola.

A gas pool is a reservoir of a more or less quantity of gas. When the gas has been drawn off, the life of the pool is ended. As the gas is drawn off, the pressure goes down. The condition is precisely analogous to that of a reservoir containing a quantity of compressed air. As the air is drawn off through a single outlet, the pressure decreases; and if it be necessary to obtain the same quantity of air, another outlet must be opened to secure it at the diminished pressure. So it is with a natural-gas pool. A few wells may for a time deliver a certain quantity of gas; but as the pressure goes down, the volume of gas delivered decreases also; and to maintain the supply, more wells must be sunk into the gas stratum.

In close connection with the gas, but in a way that is not clearly understood, is water. At the end of the life of a gas pool, water comes into the sand where the gas was originally. Sometimes the water does not come in until the gas pressure has fallen nearly to zero. In

other cases, water is a source of trouble and frequently cuts out a well when the gas pressure is still high. Why this should happen, we cannot say, but it is a fact that experience has shown. In this respect there is a considerable difference among gas pools. Some may continue to yield gas down to atmospheric pressure, or even less, in the latter event the gas being sucked out mechanically. In other pools, the gas supply of a well may be cut off by the influx of water when the gas pressure is still high, even as high as 300 or 400 pounds.

The measured volume of a gas well, or gas pool, is no criterion of its value. Measurements of volume are frequently of doubtful accuracy, and the occurrence of wells of large volume indicates merely that the sand is able to deliver its gas quickly without affording any idea of the quantity of gas existing in the subterranean reservoir. It has been the experience in Kansas that the wells of most endurance have been those of comparatively small flow that have been found in a dense sand which was the case of Iola. We have known a single well, or a pair of wells at that place, to supply large zinc smelters for three or four years. On the other hand, wells of immense volume, tapping a loose, open sand, have died out in a comparatively short time under a moderate draft.

An industrial company that is supplying itself with natural gas must, consequently, be careful and conservative in its figuring in order to be sure that what is apparently very cheap fuel is in reality cheap only at the expense of capital account. The actual cost is sure to develop in the final summing up, but inasmuch as that may be postponed indefinitely the opportunity for self-deception is expansive. The only safe course is to charge fully the gas supply with the current expenses of maintenance, and in addition make a liberal allowance for amortization to reimburse the principal invested. This allowance will be governed by the estimate of probable life of the pool, which is highly uncertain. An approximate idea may be obtained by periodical gaging of the wells tapping the pool and determining the rate of diminution of pressure. For this purpose, field observations should be made frequently and should be carefully recorded. In forecasting the probable life of a pool, however, the investor should be

given the benefit of every doubt, in this more so than with respect to any other kind of venture.

The Price of Lake Ores

With very little preliminary discussion, the prices of Lake Superior iron ore for the present season have been fixed at last year's standard. These prices, on dock at a Lake Erie port, where most of the sales are made, are \$4.50 per ton for Old Range bessemer; \$4.25 for Mesabi bessemer; \$3.70 for Old Range and \$3.50 for Mesabi nonbessemer. The base guarantees are unchanged also, being 55 per cent. iron and under 0.45 phosphorus for bessemer ores; 51.5 per cent. iron for nonbessemer ores.

The adjustment of these prices no longer possesses the importance which it once had, since they apply only to the class of merchant furnaces which do not own their ore supply; or which use local ores to some extent and buy Lake ores to mix with them. The Steel Corporation and all the larger independent companies own their mines, and the price of ore to them is the cost of mining and delivering it. The mining may be conducted by a nominally separate corporation—in fact, it usually is—but any profit or loss shown by such a subsidiary is only a matter of bookkeeping, and it is the actual cost which enters into the calculation of the value of the final product.

There are, of course, wide variations in the cost of mining in the Lake Superior region. The ton of ore can be put on the cars for a much lower immediate price at one of the large steam-shovel mines on the Mesabi range than at a Menominee or Gogebic mine where hoisting is required and where it may be necessary to handle large quantities of water. The variations are not so great, however, when the heavy preliminary expenses of stripping and preparation for open-pit mining, under the present system, are taken into account. The cost of handling and carrying the ore to a Lake Erie port are nearly uniform and are well known; they will average about \$1.60 per ton. If we take this average and add the cost of mining, there is probably, at this season's prices only a small margin left over the value of \$1 per ton for ore in the ground. That is about the current valuation of Lake ore as fixed in the transfer of the

Hill ore lands to the Steel Corporation, and must probably be assumed in any future transaction. The day of leases at 25 cents per ton royalty has long gone by.

If the cost of transportation from Lake Erie to the furnace is added, the merchant furnace buying its ore must count on a cost of \$4.50 to \$5 per ton for its ore in all its calculations for the future. It is not likely that any future reductions will be made from the prices which prevailed during the past year of light demand. It is quite probable, indeed, that costs may increase; not, perhaps, in an advance of prices, but more probably in a decrease in the guaranteed iron content of the ores.

For the present—and for the future so far as can be foreseen—the furnaces of the North must depend largely upon Lake ores. A good deal has been said of the supply of Cuban ores. These, however, are available only on and near the seaboard, where they can be cheaply delivered by water. Moreover, the Cuban ores have become practically the property of two large steel companies, and are not offered for general sale, nor are they likely to be.

The cost of mining and delivering Lake ores must long continue to be a prime factor in the cost of steel; but the nominal selling price is, year by year, of less importance.

ACCORDING TO THE U. S. Geological Survey, the number of buildings erected in the United States in 1908 was 163,087, which cost \$546,467,390. An investigation of this subject strikes us as being far from the domain of geology. The U. S. Geological Survey will better serve the mining industry by confining its attention to a study of the geology and the ore deposits of the country than by scattering its attention among miscellaneous subjects that belong to the general field of industry. The miners of the United States want more contributions of the character of the Leadville report and the establishment of more general principles, like secondary enrichment. They are not particularly interested in statistical investigation as to the cost of buildings, bridges, etc., nor the method of manufacturing shoes. At present the Geological Survey is not only missing the bull's eye, but also is failing, a good part of the time, to see the target at all.

May Dividends

In the accompanying table is shown the amount per share and total amount, of the dividends paid during May, 1909, by a number of mining and industrial companies in the United States and foreign countries.

	Location.	Amt. per Share.	Amt Paid
Amalgamated, c	Mont.	\$0.50	\$769,439
Bunker Hill & Sullivan, S.I.	Idaho	0.15	45,000
Calumet & Arizona, c.	Mich.	1.00	200,000
Camp Bird, g.s.	Colo.	0.24	196,800
Homestake, g.	S. Dak.	0.50	108,200
Interl Nickel, pt.	N. Y.	1.50	133,689
MacNamara, s.g.	Nev.	0.01	175,283
Snowstorm, s.l.	Idaho	0.03	45,000
Lehigh Coal & Nav.	Pa.	\$2.00	\$764,520
Buffalo.....	Ont.	\$0.03	\$27,000
Cobalt Central.....	Ont.	0.01	47,615
Dolores.....	Mex.	0.15	60,000
N.Y. & Hond. Ros	C.A.	0.10	15,000
Right of Way.....	Ont.	0.10	49,951
Trethewey.....	Ont.	0.10	94,545

International Nickel Company

The report of this company for the year ended March 31, 1909, shows no change in the stock issued, the amounts being **\$8,222,662** common, **\$8,912,626** preferred, and **\$54,698** stocks of constituent companies not owned. The bonded debt was **\$9,296,837**, a decrease of **\$55,000** during the year.

The income account for the year may be stated as follows:

Net earnings constituent companies	\$2,162,594
Depreciation and renewal funds	\$267,102
General expenses	139,393
Interest on bonds	475,500
Exhaustion of mines, etc.	109,205
Sinking fund reserve	177,000
Reserve for foreign consolidated companies	30,599
Special depreciation reserve	200,000
Total charges.	\$1,387,799
Surplus for the year	\$774,795

From this dividends of 6 per cent on preferred stock, amounting to **\$534,733** were paid, leaving a balance of **\$240,562**. Adding **\$2,216,799** brought forward from previous year made a total surplus of **\$2,456,861** at the close of the year.

The report of President A. Monell says: "All construction work has now been completed, with the exception of repair shop and foundry at Copper Cliff. The payment of four quarterly dividends of $1\frac{1}{2}$ per cent. each on the preferred stock was authorized by the board of directors out of the surplus earnings of the fiscal year, and they were all paid. The board has deemed it advisable to appropriate from the surplus a further sum of **\$200,000** to write down the cost of the properties, as set forth in the balance sheet. The last fiscal year followed as an aftermath of the panic of 1907, and brought with it all of the depressing conditions incident to such a state of affir-

Many of our customers worked their stocks up very close. As our sales are largely to steel manufacturers, they are susceptible to the influences which govern that industry.

"Energetic efforts which had been made in the introduction of the Monel metal commenced to bear fruit during last year, and the indications are that the production of this metal from our Creighton ores will be an important factor in the company's future operations and earnings. The American Sheet Steel Company, a subsidiary of the United States Steel Corporation, has taken up this metal vigorously. After a most severe test, the Pennsylvania railroad adopted this metal for the roof of its large terminal buildings in New York, and it has also been successfully used for propellers and many other purposes. While the tonnage is yet small, it is constantly and rapidly increasing."

Utilizing Products of Detinning Processes

Dr. Hans Mennicke describes in British Pat. 16,248 of 1908, a process for preparing, smelting and utilizing various products containing tin, particularly the metallic sponge and slime obtained by the electrolytic removal of tin from tinfoil scrap. The sponge is converted under water by stamp batteries or wet-ball mills into compact metallic lumps from which the alkali-lye is drawn. After the iron has been removed by magnetic separators, the lumps are smelted with carbon and soda, or other easily fusible salts, in externally heated crucibles, the contents of which are shut off from air. The soda or salt slag is ground and dissolved in boiling water, filtered, and the tin, dissolved as stannate, is precipitated from the liquid as oxide. The filtrate after being treated with lime can be used as soda lye, or sent back as electrolyte direct into the detinning process. Some of the new features claimed are, the obtaining of granular metallic tin and of raw tin free from iron, besides the possibility of completely converting the flying dust and the recovery of valuable products.

The making of tinfoils originated in Bohemia, according to a recent paper by William F. Gray, hammered iron plates having been coated with tin in that country some time before the year 1600. Tinfoil-making was introduced in England in 1605, the tin being brought there from Saxony. In France the first tinfoil factory was established in 1714. The first American manufacture of tinfoils in the United States was at Pittsburg, in 1831, but the industry did not develop until 1840.

Smelting a Pulverized Iron Charge

Carl G. T. de Laval, of Stockholm, Sweden, describes (U. S. Pat. 913,495, Feb. 13, 1909) a method for reducing iron from a finely pulverized charge of iron ore, carbon and slag-producing agents, the thin layer of the charge being brought in contact with a heated surface whereby

The Engineering & Mining Journal, N.Y.

DE LAVAL FURNACE

the reduction is carried out. A vertical section of the apparatus employed is shown in the accompanying illustration. The pulverized charge from the hopper is fed to the center pipe by a screw conveyor, falls through the pipe to a rotating disk, which spreads it in a thin layer, and is then caught by vanes and thrown toward the hot wall of the shaft. The wall is kept hot by introducing hot gases in the space between the shaft and brickwork surrounding it. The charge gradually descends and the reduction takes place as the charge comes in contact with the shaft wall. The lower part of the shaft is funnel-shaped and opens into a chamber, where the reduced charge gathers.

CORRESPONDENCE AND DISCUSSION

Publicity in Buying Equipment

The importance of making full use of publicity when about to purchase electrical or steam machinery is often little realized by the man behind the check book. In dull times, of course, manufacturers' agents are so keenly alive to the importance of even small sales that the announcement that one is in the market for equipment immediately brings a flood of advertising matter and starts many interviewing salesmen toward one's office. To refuse to make the most of publicity at such a time is to neglect the widest field of selection, to throw aside the opportunity to buy most wisely, and frequently at the lowest terms. In prosperous times it is still more important to make one's prospective wants known early and over the entire field, since in this way quicker deliveries can often be obtained.

In entering the market for a number of motors of different size, for example, if a company simply writes a few letters to the manufacturing houses which naturally come to mind, the freedom of choice is bound to be somewhat restricted. It cannot be assumed that any one company or group of manufacturers enjoy a monopoly of all the best designing in the motor field, for improvements are constantly being made in machinery of this kind, and orders for special motors are always being filled. The larger the number of special machines developed, the wider is the choice available to the consumer, and the more likely it is that each particular engineering problem will be solved skilfully.

This is not an argument in favor of multiplying special designs, for there is often a tendency toward overdoing this phase of electrical and mechanical work. In reality, the purchase of a special type of motor by another consumer than the original buyer helps to standardize the type, and in most cases paves the way toward a lower market price. Similar points apply in the purchase of a steam engine. Here the question of speed is frequently one of great importance, and it is only by considering a wide range of propositions and sizes that machinery best adapted to the conditions of load and economy can be selected.

It is a matter of but a few moments to cast aside the propositions which are plainly inapplicable to the situation, and the man who fears to canvass the entire available market through an inexpensive notice in the press simply throws away

some of his chances of obtaining the best technical solution of his problem. And it is a matter of dollars and cents in these times to do one's utmost to secure the most efficient machinery for the requirements.

Finally, the announcement that one is shortly to become a purchaser helps both the consumer and the manufacturer. If certain of the factories are hard pressed, the circulation of an inquiry through a wider field often enables the purchaser to secure one or more machines remaining in the hands of the dealers on account of the cancellation of a previous order, or else to select a machine of slightly different type which happens to be available. It is unquestionably true that the wider the range of the announcement of intending purchase, the better will be the deliveries secured. On his part, the manufacturer can do a much better business if he is forewarned as to prospective demands for his product. The cost of handling the order tends to decrease, since preparation can be made at the plant, if necessary, to turn out the apparatus more quickly and more economically. There is room for analysis in the economic relations of plant capacity, production conditions, and the times at which orders are received. The purchaser and the manufacturer each have much to gain by the practice of full publicity in approaching equipment selections.

Patenting Mining Claims

Doubtless every man appreciates the importance of the conservation of our natural resources, and none more than the mining engineer. He has seen the depletion of these resources by extravagance and waste but he knows, on the other hand, that the term waste is a relative one. Some of the methods of conservation, some of the lines that have been drawn about the uses of property, and interpretations that have recently been given existing laws are unreasonable and peculiarly irritating. These restrictions are a heritage from the Roosevelt regime, and much as we may admire that regime and appreciate some of its results, a sharp protest should be made.

I am thinking now particularly of the lines that have been drawn about the patenting of lode-mining claims. The attitude and procedure adopted by the land office in enforcing the requirements of

mineral showings on lode claims prior to patent are such as must have an effect directly contrary to that intended by the law, and are making it doubly hard for the prospector or man of small capital to secure patent at all. The federal statute on this subject provides for the "location of mining claims upon veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper or other valuable deposits" and it states that "no location of a mining claim shall be made until the discovery of the vein or lode within the limit of the claim located."

Of course, the former custom of permitting a location to be patented with no investigation of the supposed mineral-bearing lode and no knowledge on the part of the proper officers of government of the facts as to whether or not there did actually exist upon the property any mineral bearing lode at all, was unnecessarily loose and careless. This has been gradually changed from time to time until now the requirements are as much too severe as they were too simple.

The present policy of the land office seems to be to enforce strictly the letter of the federal statute and to require clear proof that the discovery of a mineral-bearing lode in place within the lines of each location has been made, before issuing patent. In carrying out this policy each claim for which patent application has been made is inspected and reported upon by an officer of the land department before the claim is approved for patent.

Under the land-office regulations now in force, the country is divided into so-called field divisions, at the head of each of which is the chief of the field division, and the inspection of mining claims is made under his direction. When an application for patent is filed in the local land office steps are taken at once to have it examined and reported upon by an inspector. If within a forest reserve inspection is made by a forest supervisor, or by someone acting under his direction, and if not in a national forest it is examined by an inspector sent by the chief of the field division. In either case the inspection is controlled by the chief, and the report based upon it may be accompanied by recommendations from him. His attitude is, therefore, of importance.

Papers relative to the case are forwarded to the general land office at Washington. If the inspection and report are favorable patent issues without unusual delay, but if unfavorable the local land officers are apprised of the fact and send a notice to the mineral claimant specifying

ing the charges made against the issue of a patent. The claimant is then required to file, within thirty days, an answer under oath to these charges, denying them, or setting forth a state of facts showing them to be immaterial, and calling for a hearing. At this hearing the Government is represented by the chief of the field division, who acts in direct opposition to the claimant. This is not his province, for the Government should not, and probably does not, desire that the claimant shall be loser in the contest, or shall be made to struggle against the concentrated power of the United States, but that he shall have justice. The local land officers before whom the case is heard decide on the evidence, which is then subject to review by the general land office at Washington.

The land department is much more exacting in enforcing the requirement that a lode be discovered within the lines of the claim than it should be, than the laws intend it to be. Recent hearings all through the Southwest, and probably elsewhere, have established this fact. In one hearing of which I happen to know, the chief, who personally represented the Government, contended for the cancellation of an entry on the ground that "commercially valuable" copper had not been discovered on the claim. And yet, according to the decisions of the courts, the size of the lode and the value of its contents are immaterial except where the mineral claimant is opposed by an agricultural claimant, a townsite claimant, or some other applicant who seeks to have the land removed from the operation of the mining laws. In the case mentioned there was no such opposition.

A chief of a field division was recently taken over the surface of the Gardner claim of the Copper Queen Consolidated Mining Company at Bisbee, where is a deep shaft and from which many millions of dollars worth of copper have been taken, and where there are many more millions remaining in the ground. But there is no trace of a mineral-bearing lode in place on the surface. He stated, in all seriousness and with no realization of the absurdity of the position he was taking, that "if this claim should now come before me for review, I should be obliged to report unfavorably." And the Gardner claim is on the formation.

Take the case of a claim where the mineral-bearing formation is overlaid by some later rock, conglomerate, or something else. It would be impossible, under the present rulings, for the government agents to recommend a patent, even though geologists might be absolutely sure, by their observation or even by drill or other examination made underground of the extension of the formation thereunder. All the Junction company ground at Bisbee, scores of claims in the Barry mountain region surrounded by productive areas, extensive tracts as Globe, and

everywhere else, for that matter, that are proved mines would be impossible to secure, except by the sinking of a shaft into the formation and by sufficient exploration therein to determine to the satisfaction of these agents that a commercially profitable lode did actually exist there.

Where will the individual, the prospector, the poor man who is trying to develop and sell properties come out in such a case? He must give up and let some strong concern take up his lands and develop them. Such, I take it, was not the intention of the framers of the mineral laws of the United States. This extreme position taken by the land department now seems to be the rule everywhere. It is unwarranted, unjust, illegal and a distinct hardship to those who are trying to develop the mineral resources of the West.

Slime Filtration

In the JOURNAL of May 15, 1909, appeared an interesting article on "Improvements in the Treatment of Slime by the Vacuum Filter Process," by Arthur W. Allen, of the Palmarejo & Mexican Goldfields Company, referring to certain innovations in connection with slime filtration. He has, however, omitted to say that the filter referred to is a Butters filter. The modification described illustrates one of many possible variations from the usual practice. We know of several modifications of the Butters filter that have been made by independent users and it might be of material help to the industry if others would follow Mr. Allen's example and make known interesting variations in the practice of slime filtration.

Rustless Iron

An interesting subject was touched upon by Mr. Cushman at the Iron and Steel Institute meeting recently held in this country; it was mentioned that in the past in India, the secret of nonrusting or nonoxidizing iron was known to skilled workers at that time, but has become a lost art to modern metallurgists. The monument at Delhi was mentioned, as an example for all time of the knowledge of those past masters in preventing iron from rusting, which at present is deplored as great wastage. Now we know India is famed for the purity of its iron ores ranging from the northern mountains of Kumaon to the extreme south of the Madras Presidency. The chief difficulty in smelting iron ores in India is that the three necessary elements, viz., the ore, flux and fuel,

are not sufficiently near to each other. Another great drawback is the large amount of ash contained in the coal (over 20 per cent.) But returning to the rustless monument at Delhi and the process, of which those experts the Moors and the Hindus have held the profound secret, can any of the readers of the JOURNAL give any further details of this monument at Delhi? Has anyone experimented to prevent iron from rusting by furnace work, chemical treatment, etc? My own experience and experiments in this direction have resulted thus far only in retarding the oxidation.

Electrolytic Production of Metallic Calcium

In British Pat. 24,396 of 1907, recently issued, S. O. Cowper-Coles describes an electrolytic process for obtaining calcium deposits upon one or more rotating disks of graphite or iron in proximity to the fused salt, such as calcium chloride, contained in a crucible at the bottom of which is a layer of molten metal preferably lead forming the anode connection. In the furnace the calcium chloride is first introduced into the calcining chamber, then passes into the fusing chamber, from which it flows in a molten condition to the crucible with the disks, these being rotated by electric motors or other suitable means. Mr. Cowper-Coles also proposes to use in the electrolytic separation of metals from fused salts a rotating cathode in the form of a disk immersed in the fused salt. This, however, would not be suitable for the production of metallic calcium, owing to the fact that the deposited calcium would be redissolved by the electrolyte.

In British Pat. 6029 of 1908, the Company Bismarckhütte describes a method of improving steel produced in electric furnaces. The steel previously refined in a basic electric furnace is passed into a crucible with an acid lining and allowed to settle. A mechanical readjustment takes place, the steel taking up silicon, and a favorable influencing of the internal structure of the steel is claimed. In addition it permits the production of iron alloys in a controllable manner, or the addition of modifying agents. The latter is accomplished by passing the unalloyed steel into the crucible before adding the modifying constituents.

The United States production of antimony ore for 1908, as shown by reports collected for THE MINERAL INDUSTRY, was 360 short tons as compared with 210 short tons in 1907; the value of the 1908 output \$19,800, as compared with \$28,432 for 1907.

The Analysis of Oklahoma Blendes

By L. T. MERRILL*

The ordinary methods of zinc-ore analysis are not applicable to the ores of the Miami district because of the variable results produced by the bitumen and natural oil which is never absent. Until this was recognized and the proper remedy applied the chemists of the Joplin district were wont to report results of such great variability that they were frequently bewildering.

The first two cars of this ore analyzed by our laboratory (September, 1908), gave the following results: No. 1, sellers' analysis, 44.7 per cent. zinc, 3.0 iron; buyers' analysis, 42.6 zinc, 7.7 iron. No. 2, sellers' analysis, 44.8 zinc, 2.7 iron; buyers' analysis, 45.1 zinc, 4.5 iron. This made a difference of \$6.20 and \$2.10, respectively, on every ton of ore. I may say here that any difference in analyses over \$1 per ton is not ordinarily tolerated.

A series of analyses run on these two samples was only negatively successful, the results varying to such an extent that it was evident that something, most probably the method, was at fault. An exhaustive complete analysis showing no striking dissimilarity between these and other ores of the Joplin district which caused no trouble, the bitumen and oil was evidently the disturbing factor.

To get rid of this oil was naturally the first expedient. The weighed charge was slowly brought to a red heat in a porcelain crucible, cooled, transferred to a flask, and the analysis carried out by the usual method. The results were most startling; all irregularities ceased, the results checking closely, but in every case the iron percentage obtained was higher than that shown previous to the preliminary heating, the difference being generally from 1 to 5 per cent. The irregularities in the zinc analyses ceased, but no very marked differences were manifest.

Subsequent investigations have shown that the oil and pitch surround particles of the ore (chiefly the marcasite and pyrite) and prevent reduction by the acids. This roasting method has since become almost general throughout the Joplin district and with uniformly good results. The following is a brief description of this method as practiced in our laboratory:

SCHEME

The ore ground impalpably fine in an agate mortar, is weighed into a porcelain crucible of about 20 c.c. capacity; in this it is brought very slowly (to avoid any decrepitation) to a low red heat. The crucible and contents are then cooled and the ore transferred to a "copper determination" flask of about 200 c.c. capacity

by means of a small camels'-hair brush. Decomposition of the ore is effected by 8 c.c. of 1:1 hydrochloric and nitric acid. When complete, 3 to 4 grams of chemically pure ammonium chloride are added and the contents allowed to boil until intumescence occurs; 50 c.c. of hot water is then added and when all is in solution, 7 c.c. of ammonia. The contents are brought to a brisk boil, then filtered into a No. 3 beaker.

The ferric hydrate, etc., is well washed on the filter with a hot dilute solution of ammonium chloride. After thorough washing the ferric hydrate is dissolved with 1:5 hydrochloric acid into the original flask through the filter, the filter washed, the iron precipitated with 5 c.c. ammonia and boiled and the filtering repeated. The filtrate is then acidified with 15 c.c. hydrochloric acid, warmed and titrated with standard $K_2Fe(Cu)_6$ solution.

The chlorides are washed from the precipitate of ferric hydrate, which is then dissolved into a clean flask with 1:5 sulphuric acid; a few grams of granulated zinc are added, the contents brought to a boil, taken off, allowed to stand until the zinc is all dissolved, and the solution cold. Then titrate with standard $KMnO_4$ solution.

Finished Iron and Steel Production

The American Iron and Steel Association has just published statements of the production of finished iron and steel in 1908, which serve further to show the trade depression of the year. The production of rolled iron and steel in various forms is given below, in long tons:

Products.	Iron.	Steel.	Total.
Rails	71	1,921,540	1,921,611
Structural shapes	2,423	1,080,758	1,083,181
Plates and sheets	54,033	2,595,660	2,649,693
Nail plate.	15,482	30,265	45,747
Wire-roads	509	1,816,410	1,816,949
Rolled forging blooms and forging billets	282	121,039	121,321
Merchant bars	685,238	1,301,005	1,986,243
Skep, flue, etc	297,049	833,531	1,130,583
Splice-bars	10,502	81,308	91,810
Hoops	1,000	169,860	170,860
Bars and cotton-ties	293	238,148	238,441
All other.	171,572	380,383	551,955
Total	1,238,449	10,590,340	11,828,789
Total, 1907.	2,200,086	17,664,736	19,864,822

Of the plates and sheets reported last year 1,271,021 tons were classed as plates, being No. 12 gage and thicker; 1,378,072 tons were sheets, No. 13 gage and thinner.

While exact figures cannot be given, as the two reports are in different forms, it is approximately correct to say that the United States Steel Corporation last year produced 55 per cent. of the total finished iron and steel made and sold.

The total decrease in rolled products last year was 8,036,033 tons, or 40.5 per cent. The production of rails has been heretofore given in detail.

NAILS

The production of nails of all kinds for two years past was as follows, in kegs of 100 lb. each:

	1907.	1908.	Changes.
Cut Wire	1,109,138	956,182 D.	152,956
	11,731,044	10,662,972 D.	1,068,072
Total	12,840,182	11,619,154 D.	1,221,028

All the wire nails and 646,062 kegs of the cut nails were made from steel. Last year wire nails were 91.8 per cent. of the total, and cut nails 8.2 per cent.

The nail make showed a much smaller decrease than any other form of steel, except tinplates.

TINPLATES

The production of black sheets and of finished tinplates and terne-plates is reported as below. The black sheets are the plates rolled for coating with tin. The figures are in long tons:

	1907.	1908.	Changes.
Black plates	504,072	513,771 I.	9,699
Finished:			
Tinplates	444,933	468,257 I.	23,324
Terne-plates	69,842	68,829 D.	1,013
Total	514,775	537,086 I.	22,311

Of the black plates rolled in 1908 only 2954 tons were of iron. Tinplate production was the only form of iron or steel which showed increased production last year.

CHARCOAL IRON BLOOMS

The production of iron blooms, billets and bars in charcoal bloomaries from pig iron or from pig iron and scrap, for the consumption of the makers or for sale, amounted in 1908 to 55,073 tons, against 84,023 tons in 1907 and 94,099 tons in 1906. The charcoal iron blooms, slabs, etc., produced in 1907 and 1908 were made in Pennsylvania, Maryland, Kentucky and Ohio. In 1900 these products were made by these four States and Delaware. Charcoal iron blooms are chiefly used in the manufacture of skep for boiler tubes and in the manufacture of black plates for terne plates. About four-fifths of the annual production is consumed by the makers.

Forges for the manufacture of blooms and billets from iron ore have not been in operation in the United States since 1901, in which year the blooms and billets so made amounted to 2310 gross tons, all made in the State of New York. All the Catalan forges in the United States have long been abandoned.

The only charcoal blast furnace in England is at Backbarrow in Cumberland. It was recently relined and repaired, and went into blast again early in May. It has been in operation over 60 years.

*Chemist, Cockrill Zinc Company, Webb City, Mo.

HIGH-TENSION UNDERGROUND ELECTRIC CABLES. By Henry Floy. Pp. 135. illustrated. 5x7½ in.; cloth, \$2. New York, 1909: Electrical Publishing Company.

SANITATION AND SANITARY ENGINEERING. Revised Edition. By William Paul Gerhard. Pp. 174. 5x7½ in.; cloth, \$1.50. New York, 1909: Published by the author.

THE MANUFACTURE OF EXPLOSIVES. Twenty Years' Progress. By Oscar Guttmann. Pp. 84, illustrated. 6x9 in.; cloth, \$2. New York and London, 1909: Whittaker and Company.

SECOND REPORT ON THE CLAY DEPOSITS OF GEORGIA. By Otto Veach. Geological Survey of Georgia, Bulletin No. 18. Pp. 453, illustrated. 7x10 in.; cloth, Atlanta, Ga., 1909: Geological Survey of Georgia.

INVESTIGATIONS OF THE COALFIELDS OF WYOMING BY THE UNITED STATES GEOLOGICAL SURVEY IN 1907. By J. A. Taff, E. W. Shaw, C. W. Washburne, E. G. Woodruff, E. E. Smith, M. W. Ball and A. R. Schultz. U. S. Geological Survey, Bull. No. 341B. Pp. 282, illustrated. 6x9 in.; paper. Washington, 1909: Government Printing Office.

THE RHODESIAN MINER'S HANDBOOK. Revised Edition. By F. P. Mennell. Pp. 167, illustrated. 5¼x8½ in.; cloth. Bulawayo, Rhodesia, 1909: Ellis Allen.

Contents: Geological formations. The origin of ore deposits. Character of orebodies. Prospecting, etc. Work with the blowpipe. Precious metals. Base metals, etc. Precious stones. Coal. Working notes.

ALLOYS AND THEIR INDUSTRIAL APPLICATIONS. By Edward F. Law. Pp. 269, illustrated. 5½x9 in.; cloth, \$4. Philadelphia, Penn., 1909: J. P. Lipincott Company; London, Charles Griffin & Co., Ltd.

Contents: Properties of alloys. Methods of investigation. Constitution. Influence of temperature on properties. Corrosion of alloys. Copper alloys (bronze). Copper alloys (brass). Copper alloys (special bronzes and brasses). German silver and miscellaneous copper alloys. White metal alloys, lead, tin and antimony. Antifriction alloys. Aluminum alloys. Silver and gold alloys. Iron alloys. Miscellaneous alloys.

PRINCIPLES OF MINING. By Herbert C. Hoover. Pp. 190, illustrated. 6x9 in.; cloth, \$2.50. New York and London, 1909: Hill Publishing Company.

Contents: Valuation of copper, gold, lead, silver, tin and zinc lode mines. Development of mines. Stopping. Method of supporting excavation. Mechanical equipment. Ratio of output to the mine.

Administration. The amount of risk in mining investments. The character, training, and obligations of the mining engineering profession.

This book is appropriately entitled the "Principles of Mining" because it deals with the fundamentals of the art from the economic standpoint, and that, of course, is the only reason why mining is prosecuted at all. The great treatises that discuss in detail the technics of the art concern themselves with the means how. Mr. Hoover treats broadly of the means how, but confines himself chiefly to the reasons why, and so far as we are aware he is the first author to take up that elemental phase of the subject. It has been done, of course, in a fragmentary way in contributions to the technical press and the proceedings of the societies, but no one previously has elaborated a treatise upon it. It is singularly fortunate that Mr. Hoover should be the first to elect to do so, because we can conceive of no one else so thoroughly competent. He is so well known in the profession and in the industry at large that it is unnecessary for us to expand respecting his capacity. It is sufficient for us to say, and this merely for the information of the laymen, that he is not only eminent as an engineer, but also as a manager of mining enterprises of the first magnitude in many parts of the world. The profession and everyone interested in the mining industry are to be congratulated that he has taken the trouble to write this book.

BUILDING CONSTRUCTION AND SUPERINTENDENCE. Part I, Revised Edition. By F. E. Kidder. Revised and enlarged by Thomas Nolan. Pp. 965, illustrated. 7x10 in.; cloth, \$4. New York, 1909: William T. Costcock.

Contents: Foundations on firm soils. Foundations on compressible soils. Masonry footings and foundation walls. Shoring and underpinning. Limes, cements and mortars. Building stones. Cut-stonework. Bricks and brickwork. Architectural terra-cotta. Fireproofing of buildings. Concrete and reinforced concrete construction. Iron and steel supports for masonry—skeleton construction. Lathing and plastering. Specifications.

It is unnecessary for us to enter into any description of this well known work, which for many years has been a classic among architects, engineers and builders. It was Mr. Kidder's intention to publish a thoroughly revised edition, but personally he was unable to undertake it. Shortly before his death he expressed his wish to his friend, Thomas Nolan, assistant professor of architecture in the University of Pennsylvania, that he should do it. In carrying out that wish Professor Nolan endeavored to bring it down to the present day in such form that it will continue to hold a high place as one of the best contemporary

practice in the elements of architectural masonry construction and superintendence. In the execution of that idea he has been entirely successful. There has been an entire revision, and many new chapters have been supplied. The book will continue to hold its place as a classic, with the additional advantage of being thoroughly up-to-date. Of course, it is a work that no architect or builder can afford to be without. We may add that it is of the highest importance to constructing engineers in general practice, many of whom do not possess the acquaintance with it that they ought.

CRELLE'S CALCULATING TABLES. New Edition. By O. Seeliger. 10x15 in.; cloth, \$4. Berlin, 1908: George Reimer.

This book is useful chiefly for tabular computation where many numbers are to be multiplied by the same factor. It gives directly, without further calculation, the products for the multiplication of every two numbers from 1 to 1000, quotients up to 1000, obtained from divisions, and the application to multiplication and division of all numbers above 1000. Methods are given for readily obtaining square, cube, and biquadratic roots. The tables enable procedure with three figures at a time, in obtaining roots, instead of with one at a time, as in ordinary calculating. Each page contains 2000 products, i.e., those of each of the two factors at the top of the page with all numbers from 1 to 1000. In multiplication the hundreds of the second factor are found along the same horizontal line as the first factor, at the top of the page. The tens and units in a column to the left of the page. The product is found by following down the hundreds column to the horizontal line of the tens and units. The last two figures are placed apart in the last vertical column to the right of the page, as they are the same for all products given on the same line.

In dividing, the nearest product below the one given is found on the page of the other number. (One of the numbers is considered as the dividend, the other as the divisor.) The heading of the column under which the product is found gives the hundreds of the quotient and tens and units are found on the same horizontal line, in the last column to the left of the page.

These tables have been rearranged so as to be much more convenient and so as to minimize the chances for errors entering the work. Originally the tens-multiples of any factor were omitted. These have been supplied in the present publication so that products of all multiples of tens can be directly read off. Other alterations have been made to make the tables more complete and easy of manipulation. They are of great use to engineers and others who have to make many computations. The price is surprisingly cheap considering the magnitude and character of the work.

Devices for the Prevention of Overwinding

Several efficient combinations of throttle-closing devices and automatic brakes have been invented and patented by the Sullivan Machinery Company. Where these are in use, writes S. T. Nelson, superintendent of the Chicago Works of the Sullivan company, in *Mine and Quarry*, a dangerous overwind is practically impossible. Someone not familiar with these devices may ask the question, "In case of a lower boiler pressure than that for which the hoist is intended, if the throttle is closed at the same point as it would be closed if the boiler pressure were higher, will not the engine come to a standstill before the landing is reached?" Regarding this, it should be explained that after the main throttles are automatically closed the engineer cannot reopen them until the engine is reversed. Should it be necessary to admit more steam to the cylinders a small bypass throttle is provided for this purpose, connected with the operator's platform by means of a hand lever or foot treadle. From this small throttle the steam is conveyed to the main cylinders through a pipe varying from 1 to 2 in. in diameter according to the size of the machine, and a sufficient amount of steam is admitted to the cylinders to complete the lift without increasing the speed of the engine beyond one at which the automatic brake can safely be applied. The automatic closing device is so adjusted that with the heaviest boiler pressure and the lightest load the engine will come to a standstill, or nearly so, before the point is reached where it is desired to apply the automatic brake and stop it entirely.

The bypass throttle is also very convenient to use instead of the main throttles when hoisting officers and miners or examining the shaft. Due to the small size of the bypass throttle and the small amount of steam admitted through it, a large hoisting engine can be much more conveniently controlled with it than with the large throttle.

The automatic throttle-closing device is not only a means of safety, but a means of economy as well. A great many hoisting engineers will not shut the throttle until late in the trip, at least part of the time. The hoist is then running at such a speed that the brake has to be applied to arrest the momentum long before the landing is reached, whereas had the throttles been closed several revolutions earlier that much steam would have been saved, instead of being wasted in the neutralization of its energy by the brakes.

Several instances are recorded in which the hoisting engineer has come up to a level, taken on a load and, by mistake, reversed the engine and lowered the load, instead of hoisting it. The down-going skip pulled the engine backward at full speed, with the steam admitted to the

cylinders in the same direction, thus acting with gravity, instead of against it.

But even though the speed of the machine was controlled by the down-going weight and not by the steam, the automatic brake was applied, and with the exception of breaking a part of the overhead sheave, no damage was done. Had not the automatic brake gone into action the loaded down-going skip would have shot the empty up-coming skip through the top of the shaft house.

Salt Production with Exhaust Steam

By NORMAN B. BEASLEY*

There is now going on in the salt industry, especially in Michigan, a transformation almost as radical as occurred when Michigan lumber first brought out Michigan salt. It is a change from the saw-mill system of producing salt, in which fuel economy was no object, to a time that is almost here when fuel will be the main consideration. Much of the

of the brine as evaporation proceeded; (3) to ascertain the amount of brine required to make a barrel of salt; (4) to record the fluctuations in steam pressure, pressure of the atmosphere, temperature of the air above the grainer, and temperature of the outside air in order to show, if possible, the effect of these items on the economical production of salt.

No attempt was made to secure especially favorable conditions, the plant being run during the test exactly as the salt maker had been accustomed to run it. The salt was obtained from a natural brine and the steam for the salt plant was exhaust steam from a factory, the pressure averaging 1.6 lb. per sq. in. and containing 3 per cent moisture. The test was divided into eight intervals as shown in the accompanying table. The rate of condensation was at first rapid and fluctuated considerably for the first 9 hours at which time the salt was being raked out. The rate of condensation for the next 37 hours, period No. 2, was approximately uniform, but changed to a different rate, which was substantially followed for the ensuing 53 hours.

BRINE EVAPORATION WITH EXHAUST STEAM.

Period.	Hours.	Salt, Pounds.	Steam, Pounds.	Pounds per Hour.		Pounds Steam Required to Produce One Pound Hot Salt.
				Salt.	Steam.	
1	9		26,320		2,924	
2	37	25,207	91,354	684	2,466	36.05
3	53	32,969	110,570	623	2,086	33.48
4	17½	11,783	39,396	673	2,245	33.36
5	34½	20,896	69,286	605	2,008	30.1
6	4	2,468	17,594	617	1,808	30.76
7	24	10,640	35,452	443	1,477	31.8
8	13	6,900	24,040	531	1,849	34.9

future salt supply of this section is destined to come from mineral fuel, in which case its cost directly becomes an important factor in the salt production, or indirectly, as in the case of a salt works using exhaust steam from a manufacturing plant. Either of these situations forces upon the salt producer a realization of the fact that steam costs money. Economy and efficiency then become important factors.

Steam economy and evaporative efficiency are subjects that are always of interest and there is a relatively small amount of literature on the subject of brine evaporation available for general reference. To secure reliable data on this subject, George B. Wilcox, of the Wilcox Engineering Company, Saginaw, Mich., made a number of evaporative tests on salt-producing apparatus of different kinds. Some of these tests were made on salt grainers. The objects of the test were: (1) To determine the amount of steam required to produce a barrel of salt—28½ lb.; (2) to record, for future reference, the variations in temperature

By comparing the total steam condensed in any period with the total salt produced in that period, we obtain the pounds of steam required to produce a pound of salt during a given period. Knowing the cost of the steam we can find the cost of producing a pound of salt during each of the given periods, and an analysis of the conditions existing during that period gives us an insight into the conditions required for economical production. There were many variable conditions, such as specific gravity of the brine, changes in ventilation in the grainer room, agitation of the brine surface, and depth of brine above the grainer pipes. These data are not available at the present time but a study of the general results given in the table will perhaps prove illuminating.

The 1908 production of the silver in the United States, according to figures of THE MINERAL INDUSTRY, only amounted to 51,798,053 oz. (\$27,382,523) against 56,514,700 oz. (\$30,010,358) in 1907. The low price of the metal in 1908 curtailed the output.

*Detroit, Mich.

Personals

Mining and metallurgical engineers are invited to keep *THE ENGINEERING AND MINING JOURNAL* informed of their movements and appointments.

C. Colcock Jones has been at Manhattan, Nev., examining placer ground for Los Angeles people.

Frank Huntziker is now connected with the office of Victor Rakowsky, at Duluth, Minn., as associate engineer.

Victor Kerr has been appointed superintendent of the Gold King Mining Company at Silverton, Colorado.

Eli T. Conner has opened an office in the Real Estate Trust building, Philadelphia, Penn., as consulting mining engineer.

D. M. Haynes, of Golden, Colo., has gone to Yucatan, Central America, to look over mines in the interests of eastern people.

J. H. Robeson has been appointed general manager of the Dives-Pelican and Seven-Thirty mines at Silver Plume, Colorado.

J. A. Whittier, manager of the Good-enough mine, Slocan, B. C., has returned to Nelson, B. C., from California, where he spent the winter.

Burr & Fergusson, civil, hydraulic and mining engineers, have opened offices in the Loo building, Hastings and Abbott streets, Vancouver, British Columbia.

William E. Miller, secretary of the Arizona Copper Company, and George Richmond, one of the directors, are in Clifton, Arizona, inspecting the work of the company.

Herbert Haas has left San Francisco for Salt Lake City in reference to his sintering process, and will continue his trip to Cleveland, Ohio. He expects to be gone for at least a month.

James Cronin, of Spokane, Wash., formerly manager of the St. Eugene lead-silver mine, East Kootenay, has gone north to develop a mining property in the Babine mountains, Skeena River district of British Columbia.

Arthur C. Fox has resigned as representative of the fee-owners of the Silver mine at Virginia, Minn., and has left for Clealum, Wash., where he has accepted the position of superintendent of the Duluth-Pacific Copper Company.

W. W. Keefer, recently with the Monongahela River Consolidated, has been appointed vice-president and general manager of the Pittsburgh Terminal Railroad and Coal Company, and will have charge of all the coal-mining operations.

Samuel M. Robins, for years superintendent of the New Vancouver Coal Mining Company's collieries in the Nanaimo district, Vancouver island, B. C., is now living at Ilfracombe, Devonshire, England, and has much improved in health.

Charles S. Witherell, formerly superintendent of the copper department, Perth Amboy plant, American Smelting and Refining company, has been appointed to similar position with the Balbach Smelting and Refining Company, Newark, New Jersey.

Victor Rakowsky has been superintending concentrating tests at Dallas, Tex., and from that point left for the Cascade mountains, Wash., and Butte, Mont., for the purpose of examining mining properties. He will return to Duluth, Minn., about the middle of June.

James S. Douglas, for a number of years connected with the Phelps-Dodge interests, has resigned the position of manager for that company in Sonora, Mexico, and will be succeeded by J. S. Williams, Jr. Mr. Douglas has built a house in Douglas and will move to that city from Naozari, his intention being to spend a year in traveling, during which he will visit the principal copper mines of the world.

Hon. Edgar Dewdney, of Victoria, B. C., who was engineer in charge of the work of making a road much used by Cariboo pioneers and the trail from Hope, on the Fraser river, to Wild Horse creek, the scene of another important gold rush nearly half a century ago, recently celebrated the jubilee of his arrival in British Columbia from England. Beside having been associated with much pioneer work in connection with placer gold mining, Mr. Dewdney has served as a member of the Dominion government, and has been lieutenant-governor of the Northwest Territories and of British Columbia.

Obituary

Major J. R. Graham, of London, England, technical adviser for the East Tibury (Canada) Oil Fields, Ltd., died suddenly at Chatham, Ont., May 26. Prior to entering the oil business, Major Graham saw active service with the British Army, subsequently becoming British military attache at Washington.

Francis X. Pund, vice-president of the D. T. Williams Valve Company, Cincinnati, O., passed away at his home, after a brief illness, Saturday morning, May 8, aged 57 years. He was born in Cincinnati and after service with several firms, in 1904 he entered the manufacturing business and with David T. Williams, founded the D. T. Williams Valve Company. Mr. Pund was a prominent member of various business organizations in which he took a great interest.

George C. Edson, who died suddenly at St. Albans, Vt., May 21, was recognized as an authority on geology and studied particularly the Cambrian division. Only recently he discovered what is called Middle Cambrian in Vermont, with many fossils as before found in the State. He

had long been in correspondence with the Smithsonian Institution and United States Geological Survey. He had been engaged for years under the direction of Professor G. H. Perkins, State geologist, in studying and writing of the geology of the upper part of the State.

Societies and Technical Schools

Lackawanna Chemical Society—This association held its monthly meeting May 25, in the new laboratory of the Delaware, Lackawanna & Western Railroad, at Scranton, Penn. This building, with its fixtures, will have cost about \$40,000 when complete in detail. Testing machines for metals, cement, wood and rubber hose are in place including a Reihle 200-000-lb. machine. There are fine soapstone topped chemical benches on the second floor, with a complete system of hoods, and other methods of ventilation. The Lackawanna finds that it pays to test boiler water, fuels, oils, cement, metals, paints and almost all supplies purchased in large quantities.

American Society of Engineering Contractors—This organization has a membership of about 1500, scattered over the United States, Canada and Mexico. The object is to assist engineers and contractors to better the conditions under which they work, to establish a high professional standard, obtain better contracts and specifications and to bring together on a common ground engineers, contractors and the manufacturers of engineering tools and equipments. The following officers have been elected for 1909: George A. Jackson, Chicago, president; Halbert P. Gillette, New York, first vice-president; D. E. Baxter, New York, second vice-president; Daniel J. Hauer, New York, secretary; Prof. Alex. Haring, New York, treasurer.

Coal Mining Institute of America—The summer meeting will be held at Punxsutawney, Penn., June 29-July 1. The following papers are promised:

Address of Welcome, A. W. Calloway; "The Safe Use of Electricity in Mining," George R. Wood, Pittsburgh; "Clay Mining and Its Relation to Coal Mining in Central Pennsylvania," R. R. Hice, Beaver, Penn.; "The Sociological Side of Coal Mining," C. Rae King, Crabtree, Penn.; "Mine Inspection with Respect to Car Allotment," H. B. Douglas, Philipsburg, Penn.; "The Preservation of Mine Timbers," John M. Nelson, Jr., Washington; "European Coal Mines," J. W. Paul, Pittsburgh; "The Heat of Coke Ovens," J. R. Campbell, Scottdale, Penn.; "Methods of Bringing Down Coal Other than by Blasting," William Seddon, Brownsville, Penn. Wednesday June 30 visits by special train to mining plants in Indiana and Armstrong counties have been arranged.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Denver, Indianapolis, Salt Lake City, Johannesburg

REVIEWS OF IMPORTANT EVENTS

San Francisco

May 26—The phenomenal success of quartz miners at Alleghany, Sierra county, within the past two months has been such as to attract the attention of mining communities in all the Pacific Coast States. Large numbers of men have gone to that sect on prospecting and trying to buy old properties or prospects. The region has been worked for nearly 60 years, though it has never been placed where capital has done much. Indeed, the location is to a certain extent an isolated one, there being no railroads anywhere near it, and not even good wagon roads. As a result the miners who have worked there for years have made comparatively little development as far as deep mining is concerned, and a large number of discovered prospects have remained prospects for years, until now they have taken on a value owing to the finds in several of the mines which have been properly worked. A year or more ago the finding of a large body of exceptionally rich ore in the Tightner mine, owned by H. L. Johnson, first called attention to the possibilities of the Alleghany section. Men who have gone in there since have discovered even richer and larger orebodies than those of the Tightner. Capitalists from all directions are trying to get hold of such available claims as they can. It is a Colorado man, E. H. Wilson, who has developed the richest mine of the section—the Sixteen-to-One—from which he took some \$300,000 in six weeks after the discovery in the tunnel on April 1, and the mine is still yielding largely. Mr. Wilson makes no secret of the mine's production as it is not for sale and he owns most of it.

Within the past two weeks other strikes of magnitude have been made in the Alleghany section. H. L. Johnson, owner of the Tightner, bonded the El Dorado two weeks since, and a few blasts in specimen rock loosened between \$50,000 and \$60,000 worth of gold ore. The Morning Glory mine, near by, owned by Rohrig Brothers, has broken into rock of immense value, some \$75,000 being taken out in a few days. The Rainbow mine at the same place, L. P. Woodbury, manager, has struck "jewelry" rock also. In this property they expect to cut the Tightner vein in their tunnel within a week. As may be supposed, these developments have had the effect of starting up work on a number of old and new properties in the vicinity. Not only that, but other parts of Sierra county are sharing in this prosper-

ity. The Bonanza King, a Southern Sierra property near the Middle Yuba river, has begun shipping very high-grade ore to the smelter. Ole Johnson, of Mountain House, a few miles from Alleghany, has unearthed a rich surface pocket. The Chipps mine above Sierra City is again in bonanza ore. San Francisco men, represented by F. M. Phelps, have bonded the West Point mine, seven miles from Downieville, and are opening it. The White Bear drift mine, seven miles from Downieville, has broken into high-grade gravel. The manager, John Costa, has found deep blue gravel which pans freely. The old Alaska mine, at Pike City, after five years' struggle against water, now has it under control with the big electrical pumps. The crosscut from the bottom of the new 580-ft. shaft is expected to cut the long-sought ledge soon. Manager George St. John has his mine now well equipped. The Keystone company at Sierra City has been reorganized by W. H. Perryman, T. C. Batting and others as leasers, and the mine is being worked again. The old Cleveland mine, between Sierra City and Downieville, has been bonded to John W. Shinn, of Pelham Manor, N. Y., and is being started up.

Had any of these strikes occurred in one of the southern Nevada mining camps there would have been a "rush" and wild excitement on the stock exchanges. But none of the California mines are listed on the stock boards, so that little is said in San Francisco papers about what is being done in Sierra county.

The strike of miners in Amador and Calaveras counties, over the eight-hour law, and the enforcement of the provision adopted by mineowners that men must work eight hours "at the face," at one time last week threatened to become serious. In Amador county particularly, many miners quit work. Agents of the miners' unions came to Jackson where the big mines are, and endeavored to force the employers to come to their terms, but without success. The strike has finally been settled according to terms offered by the mineowners and the men have gone back to work on the new schedule by which they use their own time, not the owner's, in going to and coming from the place they work in the mine. One of the big companies started to sell its supplies and timbers and the miners feared a general shut down of the other properties. After consultation they decided to accept the owners' offers. The same thing

occurred in Calaveras and other counties, so that it looks now as if the mineowners had won their point. No test case, however, has yet been commenced.

The tramline of the Balaklala Copper Company at Coram has been again started up and is delivering 500 tons of ore daily to the smelter. The wreck of the ore bunkers stopped matters for a month or so but the mine is again at work with 225 men on payrolls. The bulk of the fluxing ores for the smelter comes from Nevada, though some is mined at the Reid property in Shasta county.

W. S. Fletcher and associates, of Los Angeles, who have bonded a number of gravel properties on the Forest Hill and Michigan Bluff divides in Placer county, have commenced development work on them. At the Home Ticket, near Last Chance, 20 men are working on the channel. Work has begun on the Red Sea mine in Devil's Cañon and the Paragon drift mine near Forest Hill. Several of these mines are on gravel channels of proven richness but have laid dormant for want of capital to run the necessary bed-rock tunnels. They are all drift properties.

The McSe Rogers group of mines in Quartzburg district, Mariposa county, has been bonded to New York men through James F. Peck of San Francisco. They include the Washington, Franklin, Jenny Lind, No. 4, Quartz Mountain, Pool and several others. Some of these mines have been large producers and some are equipped with hoists, mills, etc. After necessary repairs the power will be obtained from the Exchequer company's electric plant on the Merced river. The mines are near Hornitos.

The Anti-Débris Association is afraid that the laws against hydraulic mining are not being obeyed, because they find that the miners are making efforts to keep the watchmen or "spies" away and keep themselves posted by telephone or otherwise when a watchman is likely to come to their neighborhood. In Placer and Nevada counties notices have been conspicuously posted, meant chiefly for the Anti-Débris watchmen. The "warning" states: "You are now on private property and amenable to law as a trespasser. Retrace your steps as speedily as possible or you will be roughly handled and subject to arrest. We are not hiring any help and do not want any sightseers. Get out and stay away. These orders will be enforced by local police officers and a detective agency."

Butte

May 26—News comes from New York that J. G. White & Co., of that city have underwritten the \$2,500,000 bond issue of the Butte & Helena Electric Railway Company, recently formed for the purpose of constructing an electric line between Helena and Butte. It is probable that work on the construction of the line will be begun immediately.

J. W. Murphy, Jessie S. Murphy, Duncan McRae and Margaret McRae have instituted action in the local district court against J. M. Kennedy and Maurice Eisenberg for the recovery of 20,000 shares of stock of the Butte Hill Copper Mining Company. In the complaint it is alleged that the defendants received the stock for no consideration for the company but that they have failed to use the stock for that purpose and have converted it to their own use. Certified articles of incorporation of the Montana, Idaho & Pacific Railway Company have been filed in the office of the county clerk of Missoula county. The company is an Idaho corporation with a capital of \$16,000,000 and was organized for the purpose of constructing a road from Lapwai Junction, Idaho, to Butte, via the Lolo pass of the Bitter Root mountains.

The annual report of the Anaconda Copper Mining Company for 1908 has recently been made public. In the report it is stated that 64,869,176 lb. of copper were produced as compared with 63,055,661 in 1907. The mines were not opened until March, 1908, and the expenses incident to the reopening were such that there was a deficit during the first six months of the year. It is stated that considerable difficulty was experienced with the mine fires in the Anaconda, St. Lawrence and Never Sweat mines but that the completion of the Belmont shaft will increase the facilities for mining the ores of those mines without interference by the fires. The report further states that long term contracts have recently been closed by which electric power for use in the Butte mines will be secured at low rates.

A decision of great importance to every locator of a mining claim within the boundaries of a national forest was delivered today by Register Miracle and Receiver Freeman in the case of the United States against Joseph Garneau and Louis Hickey, and is in favor of the defendants. This is the first case of the kind which the officials of the Helena land office have ever passed upon, and in the decision some important principles are enunciated.

Garneau and Hickey located quartz claims within the boundaries of the Elk horn division of the Helena national forest, and charges were brought against each location, alleging that there had been no discovery of mineral in rock in place. The results of samples taken by the Government expert did not come up to the

standard which he considered necessary to constitute a location.

Denver

May 28—A few years ago a pyritic smelter was erected at Golden by Dr. Carpenter, and affiliated with it at that time was the Saratoga mine of Gilpin county. From the smelter great things were expected by the producers of pyritic ore in Gilpin and Clear Creek counties; but after a short and uneventful career, it was compelled to close down. Later a new company was formed, and the smelter once more placed in blast, with abundant promises from producers of pyritic ore to keep the plant amply supplied, notwithstanding competitive rates that might be established by the American Smelting and Refining Company. The producers, however, allowed the pyritic smelter to fall short of ore, and it was again closed. The North American Smelter and Mines Company, organized under the laws of this State, has now secured the above plant, and expects to have it in operation soon. The producers of auriferous pyrite of Gilpin and Clear Creek counties again expect great benefits, and the outcome will be watched with much interest. The new corporation has taken control of the mines owned by the Banner Consolidated and its subsidiary companies in Clear Creek county, and of the Kilton Sampling Works at Idaho Springs.

The mining operations of the various camps in this State for the past week, in addition to the work of the regular producers, is largely confined to extensive preparations for the summer's work, and this has been long delayed by the abnormally late snow fall, which, at the high mines, has been continuing up to this time. The only news of special interest is that new strikes of rich gold ore have been reported in the Portland mine of the Cripple Creek district, and in the Camp Bird in the San Juan region. The Iowa-Tiger Leasing Company, of the Silverton district, has declared a dividend of 30 per cent., 20 per cent payable May 15, and 20 per cent, June 15.

The deep drainage tunnel of Cripple Creek has now been driven 9000 ft., or about two-thirds the distance to that part of the district where it is expected to tap the underground waters.

In Routt county, in the vicinity of Lay, on the projected line of the Denver, Northwestern & Pacific Railway, are some extensive gold placer deposits, which were first discovered in 1887 at the same time as the Four Mile placers near the Wyoming line. Four years ago a dredge was installed in Jay Creek valley, and about ten acres worked over, but it was not a success largely owing to the scarcity of water. The beds are light colored quartz sand. The gold is in nugget form, rather than in flakes, and is very pure, ranging from 885 to 900 fineness. Its origin is

undetermined, but the deposits lie in what appears to be a lake basin of Tertiary age. The Iron Springs Placer Mining Company, has just filed its articles of incorporation with the Secretary of State, with offices at Denver, Mason City and Chicago, and will begin systematic work this summer. The manager is A. G. Wallihan, of Lay, who has lived there for twenty years as locator and part owner in the coal beds which also underlie this territory, and which are owned by the Wisconsin Fuel and Mining Company, of Milwaukee.

The Modern Smelting and Refining Company has erected a copper smelting plant at Utah Junction near Denver and expects to be able to receive ores soon. The ores most desired are those of gold, silver and copper. Such ores containing a good percentage of iron and sulphur can be obtained from Gilpin county, and the company has already made a number of contracts with shipping mines. H. C. Reno, 610 Ideal building, Denver, is president of the company.

Indianapolis

May 31—Abraham Parks and five other coal miners have brought suit against Thos. L. Lewis, national president and other officials of the Mine Workers' Association to recover \$2000 each, as alleged damages for having expelled them from the association, depriving them of their union cards and of opportunity to secure employment. The suits are the outgrowth of the plaintiffs having been fined \$1 per day by the Vandalia Coal Company for refusing to enter the Rosebud mine after an explosion took place therein. The plaintiffs recovered by suit from the Vandalia Company the money so retained as fines, and the national officers made the amount good to the coal company because of the agreement that such a fine should be collected in case of a walkout pending differences. This led to the expulsion of the plaintiffs who now seek damages from President Lewis and others. If they win 22 other miners will likewise bring suit.

Charged with being the instigators and leaders in the riotous movement that caused the expulsion of 50 foreign coal miners from Hymora, nine American miners have been placed under arrest and are now under bond at Sullivan.

In consequence of this matter a movement has been started to appoint a deputy sheriff in each mining camp in the State to report any trouble among the miners and to make arrests when conditions warrant, in order to keep the peace and prevent racial troubles.

Salt Lake City

May 27—G. A. Overstrom, professor of mining and mill design at the Uni-

versity of Utah and the inventor of the Overstrom concentrating tables, has invented a new classifier. The proposed device depends on the different velocities of water to separate the different sizes of ore. The classifier consists of a number of parallel upright pipes fed at the bottom by a common pipe. The water flows into these pipes with greater velocity in the ones of smaller diameter and in this way the slimes are taken off in the first pipes which are of relatively large diameter and the concentrates in the last ones, which are of smaller bore.

The report of the Daly West Mining Company, for the last quarter shows receipts from ore sales of \$132,558, with disbursements amounting to \$130,652. It was necessary to draw on the reserve fund, which on March 31 amounted to \$314,630, to meet the regular dividend, the blocking of the road to the mine and the failure of the water supply lessening the receipts. The report says that the production cost will be cut down materially by the driving of a crosscut to the vein on the 1700-ft. level.

The output of the Tintic mines during the week was 209 cars. The shipments in 50-ton cars were: Ajax, 1; Bullion Beck (leasers), 2; Centennial Eureka, 42; Eureka Hill (leasers), 1; Grand Central, 5; Iron Blossom, 3; Grand Central, 5; May Day (crude ores), 2; May Day (concentrates), 2; Mammoth, 14; Sioux Consolidated, 14; Victoria Consolidated, 1; Victoria, 4; in 20-ton cars; Beck Tunnel, 5; Brooklyn, 6; Colorado, 26; Dragon Iron, 33; Iron Blossom, 44; Swansea Consolidated, 2.

As a result of several conferences with Gifford Pinchot, chief of the forest service, the committee of the American Mining Congress on mining in the national forests has received an encouraging communication from Chief Pinchot, outlining the friendly attitude of the forest service toward legitimate users of timber and giving a resumé of the instructions recently sent to the members of the forest service on this subject. Mr. Pinchot said in part: "I hope that these new instructions will remove any possible doubt as to the friendly interest of the forest service in the mining industry. The service desires that men engaged in prospecting or developing mining claims in the national forests should have a liberal free use of timber from the forests, if the timber on any claim is not sufficient for its development, so long as it is a prospect and not a producing mine. When a prospect becomes a mine and begins to produce ore, it is then a commercial enterprise and no more entitled to free use of government timber than any other business. This policy will be followed in the administration of the national forests, and a conveniently accessible and permanent supply of timber for mining will be provided whenever practicable."

Toronto

May 27.—The Canadian Pacific railway is commencing boring operations for natural gas at Bassano, Alta, 83 miles east of Calgary. Eugene Coste, of Toronto, has been engaged for some time in making an examination of the field, and has reported that he is convinced that gas occurs in large quantities. He is of opinion that a series of gas pockets follow the same strata as that from which the Old Glory well on Bow island, Medicine Hat, gets its supply. The company will also undertake drilling for oil at Bow island. If gas in paying quantities is struck at Bassano it will be piped to Calgary.

D. D. Cairns and party, from the Geological Survey, have left to conduct investigations in the copper-, silver- and gold-fields of the Watson and Wheaton districts in the southwestern section of Yukon territory.

The Ontario Government has appointed H. W. Richardson, R. V. Rogers and T. W. Nash, of Kingston, and Prof. Willet G. Miller, of Toronto, as its representatives on the board of governors of the Kingston School of Mining.

Johannesburg

May 5.—Eight years ago the two boreholes put down by the Turf Mines, Ltd., (recently amalgamated with the Village Deep) cut the Main Reef series and provided important testimony as to the persistence of the Rand gold carriers to a depth of over 4000 ft. For various reasons the sinking of a shaft to exploit the property was delayed, but the first sod was cut and sinking commenced in June, 1906. It was then estimated that the series would be reached at a depth of 3700 ft. In April, of this year, the forecast was confirmed with creditable accuracy by the intersection of South Reef at 3756 feet.

Unfortunately the reef disclosed is narrow and of poor grade. There are good reasons, however, for not allowing this fact to cause anxiety as to the future prosperity of Central Rand deep levels, quite apart from the danger of considering a single shaft exposure as a reliable sample for the valuation of a large area. The experience of the Village Deep workings alone, and of development in the neighboring City Deep, has gone to indicate a distinct falling off in the average grade of the South Reef, but an equally marked compensation in the higher gold contents of the underlying Main Reef leader. This reef should be cut in the Turf shaft two weeks after passing the South Reef. The announcement of poor assays from the South Reef at this depth would doubtless have had a depressing influence upon Rand mining, had it not been proved by thousands of feet of development in the City Deep that the theory of gradual impoverishment with depth is without justification. In a

less eminent degree the Village Deep itself has proved that while changes of grade may be expected upon the extension of operations on the Dip, an improvement may be looked for as reasonably as a reduction in gold contents.

Commenced, as stated above, in June, 1906, the Turf Mines shaft (or the Turf shaft of the Village Deep, as it should now be termed) has been sunk at an average speed of 114 ft. per month and, at a total cost of \$170 per ft., including all equipment. The speed does not come up to that maintained in the recently sunk Brakpan shaft in the East Rand, owing to the much more difficult formation passed through and to the use of skips instead of buckets. The Turf shaft has passed through numerous dikes, some of which, almost vertical, cut diagonally through the excavation and necessitated a special ingenuity on the part of the management to arrange hearers providing for permanent security. With the dikes, too, a great influx of water always occurs. Although no one could attempt to minimize the excellence of the work performed in sinking the Brakpan vertical shaft, its freedom from such troubles must be noted in comparative references. The employment of buckets in that case also made for great rapidity of sinking. In the Turf shaft skips were used after the initial stage with a view to greater safety. With skips, the timber sets are carried about 15 ft. from the bottom of the excavation, instead of 50 or 60 ft. with buckets.

The Turf shaft is of seven compartments—the standard for present deep levels—and measures 48x8 ft. in the clear. Its long axis is at right angles to the strike of the formation—a provision for greater strength which doubtless proved of great importance when the several stretches of troubled ground were being negotiated.

Hand labor, the cheapest and quickest means of sinking under Rand conditions, was employed throughout. There were three 8-hr. shifts, and on the average, 40 holes, 30 to 40 in. deep, were put in and blasted per shift. About 80 natives were employed each shift on shoveling and drilling. The work has throughout been under the control of Mr. Saner, manager, and Mr. Coombe, mine captain, who are now engaged in also sinking the South Rand shaft of the Crown Mines, Ltd. It has often been pointed out that these great vertical shafts will play a less important part in Rand mining than was at one time contemplated, owing to the more favored policy of amalgamation and the consequently facilitated extension of the inclines from existing verticals for the service of the deeper ground. At the same time there will still be need for new verticals in the Central Rand and the basin of the Far Eastern Rand will require many new shafts, of a depth of 3000 to 4000 ft. for its economic exploitation.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alaska

VALDEZ

Dr. E. T. Griffith, of Chicago, who has been developing important copper deposits near Landlock, has purchased machinery in Seattle, including power drills and hydroelectric plant with which to rush further operations. It is claimed that the orebody is 100 ft. in width and of a good grade.

F. H. Moffit, of the United States Geological Survey, will arrive here in a few days with a party of four men for work in the Copper river valley, while R. H. Sargent, topographer, will lead a party of seven men into the Matanuski country at the head of Cook's Inlet to make maps of the coal country.

Alaska Commercial Oil Company—This company, with offices in Seattle, has acquired ten oil claims near Katalla, and it is the intention to ship the product to the Orient. W. B. Kavanaugh is president.

Arizona

COCHISE COUNTY

Shottuck-Arizona—The mine is shipping ore from the development work on the 600-ft. level.

Copper Queen—Two additional furnaces were blown in at Douglas, making nine furnaces now in operation. The air compressor for the central power plant at the Casey shaft, Courtland, has arrived and is now being installed.

Great Western—Work has been started on a three-compartment shaft on the Mamie claim, at the upper end of the patented ground of the Courtland Townsite Improvement Company. A gasoline hoist will be installed for preliminary work. The new shaft is near the Humboldt shaft, which is one of the oldest shafts in the Turquoise district.

Shamrock—This is the name of a new town in the Chiricahua mountains, organized by the Bisbee-Sonora Development Company.

Bisbee-Sonora—The property is opened by two 340-ft. tunnels, which cut the orebody at a depth of 150 and 235 ft. respectively. Work has begun on a 600-ft. tunnel which will strike the orebody at a depth of 275 feet.

GILA COUNTY

Inspiration—Reports from the mine are encouraging. The main shaft is 800 ft. from the Miami, and is 180 ft. deep, 80 ft. of which are in a low-grade copper sulfide.

Arizona-Commercial—The concrete foundations for the new machinery will be completed within a week. The new double-drum hoist has a capacity for sinking to a depth of 1500 feet.

Cordova—Work has been begun on a new three-compartment shaft on the Eureka property.

MARICOPA COUNTY

Esperanza—R. D. Le Grand and other capitalists of Pasadena, Cal., have purchased this group of mining claims, situated three miles east of the Harqua Hala mine. Development work will begin at once.

PIMA COUNTY

Team Buttes—About 60 tons of ore per day are being taken out in development work and shipped over the company's railroad to Tucson, and thence to the smelter at El Paso.

PINAL COUNTY

El Tiro—The installation of a 250-h.p. hoist, three boilers, a compressor plant and steel headframe for the three-compartment working shaft has been completed. A 300-kw. generator is being put in, and a mill will be built soon. H. C. Smith is general manager.

Helveta—Ninety men are employed on development work. Preparations are being made to connect the Copper World and Leader shafts with a crosscut 400 ft. long. Sixty tons of ore per day are being hauled with teams to Vail, and thence shipped to the Old Dominion smelter at Globe.

SANTA CRUZ COUNTY

Leek-McDonald—The mine was recently sold to William Kemp and associates, who are now putting it in shape for ore production. J. M. Thomas, of Globe, Arizona, is superintendent. The property is 12 miles from Patagonia.

Cristle Butte—The mine is four miles from Patagonia, and will be prospected by a churn drill, which is now being put in place. The mine was recently bonded by California people, who have made partial payment.

Four Mile—The raise to connect the upper and lower tunnels at the Red Hill mine is completed. This connects the tunnel from the opposite sides of the mountain, and will give ventilation in the mine.

California

AMADOR COUNTY

Amador Mines Company—J. J. McSorley, of Mokelumne Hill, Calaveras county, has sold to the Amador Mines Company, of Amador City, the Original Amador mine for \$35,000. The mine adjoins the Keystone on the north.

BUTTE COUNTY

Carlisle—A vein which has been hunted for years has been found in this mine at Forbestown. A mill and compressor are being fitted up and a pipe-line constructed. The mine is under bond to Eugene Schmidt, former Mayor of San Francisco.

J. H. Leggett Dredging Company—At Oroville a pit is being excavated for a new dredge on 300 acres of land north of Palermo. When the new dredge is finished, the machinery of Dredge No. 3, which has worked out its ground, will be placed in it. J. H. Leggett, of Oroville, is manager.

CALAVERAS COUNTY

Boston Flat—Alcaraz & Sorensen, while working their gravel claim near San Andreas, struck a quartz claim which assays well.

North Star—The main shaft of this mine near San Andreas has been cleaned out and repaired for the inspection of men desirous of taking hold of the property.

Reiner—The new power line has been completed and steam will no longer be used.

INYO COUNTY

Four Metals Smelting and Mining Company—This company at Keeler is now running its 50-ton smelter regularly and has the properties of the Great Western Ore Purchasing Company under lease. The aerial tramway connecting mine and smelter is 5½ miles long. The upper terminal of the tramway is at the old Cerro Gordo mine. The office of this company is at San Jose, Santa Clara county; Henry T. Welch is president and A. R. Short secretary.

MADERA COUNTY

Europa—R. L. Hargrave, near Raymond, has let a contract for a 300-ft. drift which will be connected by an upraise with the upper level. All the machinery including the mill, is run by gasoline engines.

MODOC COUNTY

Cinnabar ore has been discovered in

Willow Ranch district, near Goose lake, and a number of claims have been staked, though not much development has yet been made. Fort Bidwell people are the owners.

MONO COUNTY

Quartz—The discovery of rich gold quartz 12 miles from Bodie by Edward Gray and Albert Belmont has drawn a number of prospectors from Bodie in that direction.

Snow Drift—O'Hanley, McCarty & Burnett, leasers, are taking out \$26 ore from the old workings.

NEVADA COUNTY

Empire Mines Company—At this property, Grass Valley, Geo. E. Starr manager, the first of the twin five-plunger pumps has been tested with satisfactory results. Each has a contract agreement to lift 500 gal. a minute a vertical lift of 600 ft. The pumps are to be put on the 2000- and 3400-levels as sinking to a greater depth is intended.

Ocean Star—This mine at Ormonde, four miles from Washington, has been bonded to E. C. Reed and F. U. Hubbell, of San Francisco. The latter will be resident superintendent.

Pittsburg—The new eight-drill compressor has been started at the Grass Valley mine; Mark B. Kerr is manager.

Republic—The new 10-stamp mill of this mine in Graniteville district has been started up. It is expected that the National will be consolidated with this property.

PLACER COUNTY

Big Giant—Dependener & Tyler are running an adit into this mine on a 13-ft. vein. Several rich pockets have been found.

Herman Property Syndicate—This is a new company which has taken hold of the old Herman mine at Westville. E. B. Quigley has charge. The mine has an old 10-stamp mill and a new one of 30 stamps partly finished.

Placer Queen—Cavanaugh and Cullen have struck good gravel at Robinson Flat. The tunnel is in 2500 ft. The channel is at a great altitude in the mountains.

PLUMAS COUNTY

Croton Point—Geo. McCall, one of the leasers on this property, has found a small but rich vein and ore is now being taken out.

California & Nevada Consolidated—In addition to the strike made in this mine in March, another has been made in which the orebody is large and rich.

SAN BERNARDINO COUNTY

Twenty Nine Palms Consolidated—In a shallow shaft at Twenty Nine Palms crosscut opened a 3-ft vein of ore which runs up to \$20 per ton.

SIERRA COUNTY

Brush Creek & Ante-Up—This Chicago company, which has a bond on the old Brush Creek mine, near Mountain House, is about to reopen it. When the men were driven out by water years ago there was a wide vein in the bottom of the 700-ft. shaft carrying good values. L. A. Armstrong is engineer in charge.

SISKIYOU COUNTY

Advance—This mine is about to start up again. Howard V. Lewis is superintendent.

Eastlick—The Eastlick mines and ditches at Oro Fino have been purchased at forced sale by the Reichman Company, of Fort Jones.

TRINITY COUNTY

Dorleska—At this mine, Coffee Creek, some very good ore has recently been uncovered. The mine is still isolated by the snow.

TUOLUMNE COUNTY

Esmeralda—This mine near Carters, on the East Belt, is now showing up a larger vein than was at first found, and the grade of ore is satisfactory.

Colorado

CLEAR CREEK COUNTY

Honest John—A larger air compressor is to be installed, and the company is considering the installation of an aerial tramway 7000 ft. in length, to transport the ores from the mine to the mill. J. F. Puchert, Georgetown, Colo., is manager.

Waldorf Consolidated—Another unit of 125 tons is to be added to the company's mill in the Argentine district. E. J. Wilcox, 314 Colorado building, Denver, Colo., is manager.

Gold Treasure—Denver people are interested in this property and intend to install machinery. Ira Pollard, Idaho Springs, Colo., is manager. They have recently opened up some smelting ore.

GILPIN COUNTY

Great Bonanza, Limited—This company has an option on the German Consolidated group of claims contiguous to its property. If the option is taken up larger machinery will be needed. Cecil C. Morgan, Central City, Colo., is manager.

Federal and Lilhan—Eastern people have taken hold of these properties in the Russell district, under a lease and bond, with G. Knutzen, Russell Gulch, Colo., as manager.

Gandon Mining and Investment Company—Clinton Reed and associates, of Denver, have organized this company to operate the Leavenworth mine in the Russell district. An air-compressor plant may be installed. W. C. Le Prowse is in charge.

Gomex—A four-ton shipment of excep-

tionally high-grade ore was recently sent to the sampling works. A. A. Johnson, Russell Gulch, Colo., is manager.

Labyrinth—A pool of Austrian leasers has taken hold of this Quartz Hill mine, owned by McFarlane & Sons, of Central City. Good milling ore is being obtained.

Grand Central—Rhode Island people are interested in the resumption operations at the mine on Gunnell hill. Dan MacMasters, Central City, Colo., is manager.

LAKE COUNTY—LEADVILLE

Tribune—Several months ago a lateral was started in the Yak tunnel about 100 ft. west of Ibox No. 4 shaft, to develop this vein; the lateral is now in 500 ft. and a fair body of gold-bearing ore has been encountered. The vein is from 5 to 7 ft. wide, and the trend is northeast and southwest. It is near the Little Vinnie and Little Jonny. Before this vein was encountered a body of sulphide ore was opened about 250 ft. from the tunnel, but was considered too low to ship. It is now the intention of the lessees to sink a winze on this orebody and develop it. Willis S. Brown, of Belvidere, Ill., is president of the leasing company.

South Evans Gulch—With the opening of spring a number of properties in this section have resumed work, among them being the Ella, which is shipping several cars, weekly, of oxide ore from the 150-ft. level. On other properties development work is in progress as follows. Martha, prospecting is being carried on at the 150-ft. level; Wall Street, sinking from the 100-ft. level; Crucifixion, shipping oxide from the 150-ft. level; Silent Friend, driving from Yak tunnel to connect with workings 300 ft.; Cleveland, shipping 120 tons daily; Tenderfoot and Valley, shipping, respectively, 30 and 40 tons daily; Favorite, development work is being done and the shaft will be probably sunk another 150 feet.

Garbutt—This property is shipping daily 35 tons of lead sulphide ore. The orebody is 25 ft. high and 35 ft. wide, and has been developed for several hundred feet. It is under lease to John Cortellini and associates.

Fortune—Several days ago connections were made with this mine and the Yak tunnel, and 25 tons of ore are now going out daily through the big bore, the ore is of excellent grade.

Last Chance—B. DuBois will resume work on this mine in a short time. At present surface work is being done preparatory to sinking.

Gum—This shaft belonging to the Nisi Prius company and under lease to John Harvey et al. is producing 25 tons of good lead ore daily.

Pyrenee—The large pumps recently installed have started to raise the water from the lower levels; it will take about six weeks to unwater the ground.

OURAY COUNTY

Camp Bird—Report for April: Mill ran 29 days; crushed 668½ tons of ore; produced 613 tons of concentrates and 13,357 oz. bullion; total sales, \$282,434; expenses, \$54,243; balance applicable to profit, \$228,191; development work, 672 feet.

Idaho

SHOSHONE COUNTY

The shipment of the first consignment of ore, to go all the way to the smelter by rail, was made from the Murray district recently. The shipment was made from the Black Horse mine.

Iowa

WAPELLO COUNTY

Ottumwa Iron Works—A report has been circulated through the Associated Press that this plant was totally destroyed by fire. This report probably originated from the burning of the foundry roof. The damage has not only been repaired, but the foundry has been enlarged and improved machinery added to increase the output of mining machinery.

Michigan

COPPER

Ahmeek—Arrangements have been made with the Franklin company to handle approximately 750 tons of Ahmeek rock daily. Shipments of about the same amount will be continued to the Tamarack mill. A contract has been let for the construction of the railroad spur connecting the mill with the lines of the Mineral Range railroad.

Mass—This company has reached the new lode by means of one of the crosscuts it is driving from the 15th level, but has not yet entered it far enough to determine its width or copper contents. The other three crosscuts are nearing the formation and when the lode is opened by these four points, in addition to the drift from the 17th level, which is now about 130 ft. in length, its commercial value should be practically determined.

Victoria—A continuous stretch of good ground has been opened up at the 22d level. A crosscut is being driven from the 12 level to ascertain the condition at that point. The hydraulic plant is working satisfactorily with an ample water supply.

Mohawk—Ground is to be broken by this company on the site of its new, or No. 6 shaft within a few days. This will go down in the foot wall, about 60 ft. behind the lode which it will open by means of crosscut from the various levels. Shipments aggregating about 2700 tons daily are being made to the mill from the other shafts.

Adventure—This company contem-

plates opening up the newly discovered Mass lode on its property by means of crosscuts. The crosscut from No. 1 shaft will reveal the lode close to surface and at No. 3 about 800 ft. deep. This vein has also been traced on surface by means of trenches and holds forth great promise.

La Salle—Work has been discontinued at No. 2 shaft on the Caldwell tract, after carrying on considerable exploratory work without striking any encouraging results. It is now planned to sink a new shaft between the shaft on the Tecumseh tract and No. 1 shaft of the Caldwell. No. 1 shaft of the Tecumseh is opening some very encouraging ground.

Hancock—The winze from the 13th to the 18th level, at which point it will intersect the main working crosscut from the 15th level of No. 2 shaft, is down to the 15th level. This winze is sinking on what is known as No. 3 lode and has disclosed good mineralization throughout its depth. Good ground is also being blocked out in the extensions of the drifts from the 13th and 14th levels. No. 2 shaft is sinking close to the 18th level and should cut the orebody at the 20th level, which, at the present rate of sinking, will be in August. No. 2 shaft is to have railroad facilities in the near future.

Wolverine—A fire destroyed the roof of this company's main boiler-house, but little damage was done to the boilers or compressors which were in this building. Operations were delayed only a few hours.

Missouri

JOPLIN-ZINC-LEAD DISTRICT

Goode Brothers—Plans are being made for the erection of a large mill on their lease of the Little Boss Mining Company.

Sycamore—Jones & Garvan, of Granby, have bought a mill which they will erect on the land of the Little Boss Mining Company, at Granby.

Sunrise—C. V. Millar, manager, is rebuilding the mill at Spring City, which was recently destroyed by fire.

Microbe—Adam Scott, manager, Joplin, will erect a mill on this lease at Spring City.

Delta—This mine, at Spring City, has been reopened under new management. A new shaft will be sunk.

United Zinc—The company has taken the McKinley lease on the Connor ground at Prosperity and will thoroughly drill and develop it. George T. Fletcher, of Joplin, is manager.

Silver Plume—The mill is being rebuilt and will start operations at once. Warren Heaton, of Joplin, is manager.

Herald Zinc and Lead—New and larger machinery is being installed at the mine near Cave Springs.

Cameroon—The building of the new Cameroon mill at Sarcocixie has added another producer to that already enterpris-

ing camp. The mill has a capacity of 400 tons per day and is now turning out a fair tonnage.

Cochilla—Four men were killed recently in this mine by a slab of rock falling from the roof.

Montana

BUTTE DISTRICT

Amalgamated—It is reported that at the Gagnon mine plans are being made for the sinking of a new shaft. In that event the incline shaft, 2300 ft. deep, now in use will be abandoned. For the past several years the mine has made a poor showing but recently developments indicate that the property has greatly increased in value at its present depth and that the expenditure of money necessary for the new shaft will be justified.

Butte & Superior—A strike of copper ore is reported on the 1200-ft. level at a point about 400 ft. west of the shaft. It is stated that the ore runs 2 per cent copper and 30 per cent zinc.

Copper Eagle—Work is progressing on the 350-ft. level. On this level drifting has been done 300 ft. east of the shaft and 50 ft. west. The shaft is 365 ft. in depth.

BROADWATER COUNTY

Ohio-Keating Company—Machinery has been ordered and work of unwatering the shaft will be begun shortly.

FLATHEAD COUNTY

Northern Idaho & Montana Power Company—The company has recently purchased the plant of the Kalispell Water and Electric Company. The new company plans an expenditure of \$200,000 on improvements on the plant and system of the old company.

JEFFERSON COUNTY

Jefferson Lime Company—The company has recently sold its plant and ground to the Pittsmtont Copper Company, of Butte. This is part of the plan of the East Butte company to carry on active operations at the Pittsmtont company's smelter. The ground purchased is located on the Northern Pacific Railway at Lime Spur, and the limestone will be conveyed by that road direct to the smelter of the Pittsmtont company.

LEWIS & CLARK COUNTY

East Helena Smelter—A demand has recently been made by the employees for an increase in wages of 50c. per day. While no definite statement has been given out, it is expected that the demand will be refused.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Kansas City Velvet—Another shipment is being prepared on this lease and will be sent out in a few days. The ore is

being taken from a vein 18 in. wide which runs \$60 per ton.

Goldfield Daisy—This property is now working two shifts employing between 50 and 60 men. A daily production of 10 tons is being maintained, five tons of which, coming from the 200-ft. level, runs about \$100 per ton. The balance is dump ore and assays from \$20 to \$25 per ton. Development work is being carried on in both the 300- and 500-ft. levels.

Goldfield Florence—Another tube mill is to be installed at the mill as soon as the order can be filled. This will increase the capacity of the mill about 25 per cent. At present the mill is treating from 140 to 150 tons per day. Much underground development is in progress.

Stoneman Moore—This lease, operating on the Combination No. 2 lode of the Consolidated property, will sink to the 1000 ft. level. Particular attention will be given to prospecting on the 500-ft. level where a streak of high-grade ore was recently encountered.

Grizzly Bear—A new 75-h.p. electric hoist and large gallows frame have been installed. The shaft, now 500 ft. deep, will be sunk to the 1000-ft. level. On reaching the footwall of the Clermont vein, now showing in the shaft, a station will be cut and the vein prospected.

ESMERALDA COUNTY—HORNSILVER

Great Western Mine—This property has been closed down for an indefinite period. Howard Russell, secretary and one of the principal owners of the company, is credited with stating that the mine will remain closed until better transportation facilities are afforded or a mill is constructed in the camp. The Tonopah & Tidewater Railroad is sending a corps of engineers in the field to make a preliminary survey between Hornsilver and Cuprite, the shipping point on the railroad, 16 miles distant.

LANDER COUNTY—AUSTIN

Highland Mary—George Kilborn, of Reno, has taken an option on this property which is one of the oldest in the district.

LINCOLN COUNTY—PIOCHE

Nevada Utah Mining and Smelting Corporation—This company is now shipping about 125 tons daily to the Salt Lake smelters, from its Day mine 15 miles northwest of Pioche. Superintendent Gaskill estimates that 175,000 tons have been opened up by recent development.

Ohio Kentucky—This company is negotiating with the Nevada Utah company for the purpose of reaching some agreement regarding disputed territory held jointly in Pioche. The property has been idle for nearly two years because the companies could not come to an agreement.

Prime Consolidated—This property, situ-

ated about two miles southwest of Pioche, shipped three carloads last week to the Tintic smelter. Ernest L. Godbe, of Salt Lake City, is manager, and Wm. Lloyd, of Pioche, superintendent. The shaft is now 550 ft. deep. At this level there is 3 ft. of ore running high in silver and lead.

Pioche King—Several feet of manganese ore, also carbonates and sulphide of lead, were encountered at about 180 ft. depth, the latter carrying precious metal. John A. Kirby, of Salt Lake City, is president and manager.

Golden Prince—George Cox, manager, has encountered manganese ore in the shaft at 430 ft., and in the west drift at 400-ft. level, 140 ft. from the shaft, ore showing good assay returns has been found.

Gold and Silver Prince—Dean R. Low, Pioche, manager, has just installed a new 25-h.p. Alamo hoist and compressor. The shaft is now about 90 ft. deep.

Pioche Demijohn—This property, of which Owen Bailey, Salt Lake City, is manager, adjoins the Gold and Silver Prince on the northwest. Some high-grade ore was recently found on the 125-ft. level, but it is understood to have been only in small quantity.

Pioche Metals—The property of this company, about two miles northwest of the Demijohn, is working several men and hoisting some good ore. John A. Kirby and associates control the property.

New Hampshire

COOS COUNTY

Milan Mining and Milling Company—A model B Cadillac has been transformed from the road wheels to 18-in. flange wheels for a narrow-gage railroad, and is now hauling 100 tons of ore in 10 hours from the new mill to the ore bins at the railroad siding, a distance of $\frac{1}{2}$ of a mile. The average grade is $3\frac{1}{2}$ per cent., and the cost is 4c. per ton. The new 250-ton ore-dressing, crushing and concentrating plant is now successfully adjusted and operating satisfactorily.

Oklahoma

OTTAWA COUNTY

Old Chief—This company, at Miami, will rebuild the mill recently destroyed by fire.

Mooshead—The company will build a mill on the lease at Miami.

Miami-Yonkee—L. C. Church, manager, has struck rich ore at a depth of over 200 ft. on the Emma Gordon ground, at Miami.

King Jack—Chapman & Lennan, of Webb City, are rebuilding the mill at Miami, which was recently destroyed by the explosion of the boiler.

Oregon

BAKER COUNTY

Morning Mine—The mill is treating 30 tons of ore per day averaging from \$30 to \$40 per ton. The Psyche 20-stamp mill has been purchased and will be moved to the Morning mine as soon as the roads are in condition.

South Pole—It is reported that a rich body of gold ore has been found in the main tunnel run from the Rock Spring side of the mountain. Andrew Hansen is the owner, and a five-stamp mill will be started up this month.

Utah

BEAVER COUNTY

King David—At the 300-ft. level of the shaft a big bore is being driven in a body of iron sulphides. The sinking of the shaft will be continued as the bottom indications are excellent.

Lydia—H. T. Hanks, who has been operating this property in the Star district has uncovered a large orebody. On the 50-ft. level he has drifted 60 ft. and on the 100-ft. level has drifted 35 ft., all in ore. A gasoline engine and other machinery is being installed to hasten the work.

SALT LAKE COUNTY

Columbus Consolidated—The new pump is being taken to the mine at Alta and will be in commission early in June. The new pump weighs 30,000 lb., has a capacity of 800 gal. per min. and is run by a 150-h.p. motor.

SUMMIT COUNTY

Silver King Consolidated—Manager Solon Spiro, 426 Atlas block, Salt Lake City, visited the mine recently and reports that a winze being sunk from the south drift on the 1100-ft. level is now in good ore. The wagon road to the mine has been cleared of snow and the mine will be able to ship at once.

TOOELE COUNTY

Old Glory—The wagon road to Wendover on the new Western Pacific has been completed and the shipment of the high-grade ore will start at once. With these transportation facilities available, the company will now install a compressor plant and machine drills and increase the force at the mine. D. L. Fulop, 216 Dooly block, Salt Lake City, is president of the company.

Washington

KING COUNTY—BERLIN

Miller River and Money Creek districts are coming to the front through the operations of the Apex, Seattle Cascade, Excelsior, Surwalk and the Cleopatra properties.

Seattle Cascade—This company is installing a 115-h.p. power plant, with an air compressor to correspond, and within 10 days will be equipped to carry on development work.

SNOHOMISH COUNTY—EVERETT

Nonpareil—In the Index district this company is surveying 35 claims for patent under United States Deputy Mineral Surveyor Hans Mumm, who resigned the position of city engineer of Everett to take up this work.

Northwestern Consolidated—An order for 6000 ft. of steel wire cable for an aerial tram near Monte Cristo, and a complete telephone system to connect with the terminus of the railroad has been placed by this company. J. C. Morton is manager of the company.

Canada

BRITISH COLUMBIA—QUEEN CHARLOTTE ISLANDS

Awaya, Ikeda & Co.—Another big ore-body has been encountered in the lowest tunnel (No. 3) of the Japanese company's mine at Ikeda bay, Moresby island. The tunnel is 40 ft. in ore and the footwall not yet reached. The ore averages about 5 per cent. copper and \$3 per ton in gold. Shipments are being made to the Tyee Copper Company's smelter at Ladysmith, Vancouver island.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ended May 22 were: Coniagass, 64,300 lb.; Crown Reserve, 126,400; Kerr Lake, 203,760; King Edward, 43,130; La Rose, 291,400; McKinley-Darragh, 50,670; Nipissing, 453,850; Peterson Lake, 67,580; Right-of-way, 249,130; Temiskaming & Hudson Bay, 60,000; total 1,610,220 pounds.

YUKON TERRITORY—DAWSON

In a previous issue reference was made to the early breaking up of the ice in front of Dawson, permitting local navigation. Fifty-Mile river, a branch of the Yukon, is now open from White Horse to the head of Lake Lebarge, but the lake itself is still frozen. At Hootalingua the river is also breaking up. It is expected that navigation will open June 9 for the whole length of the river.

The copper deposits of the Yukon adjacent to the Bonanza properties of the Guggenheims have gained official recognition through an examination by a government mining engineer, A. J. Baudette, whose visit was by instruction of Governor Henderson.

Last year the largest navigation company operating on the Yukon received \$73 per ton for cargo from Seattle to Fairbanks, while this year the rate is \$65, while another company is quoting rates of \$50. The opinion prevails that with the temporary cut in rates due to competition will be of immense benefit for this season, the final result will be a little higher, and yet much lower than in previous years.

Bonanza Creek—Claim No. 39 below on Bonanza has been staked by C. W. Cornish, of the Yukon Gold Company. This claim was allowed to lapse in 1908 and recent investigation pursued quietly proved the claim to be of great value.

Bonanza Creek Gold Mining Company, Ltd.—The Guggenheims have acquired the properties of this company, formerly known as the Weinheim company, which operated under the concessions granted to Matson & Doyle.

Dome Lode Development Company, Ltd.—The Guggenheims have taken on new life through the appointment of D. J. McDonald as manager; formerly of Le Roi Mine of Rossland. This is considered significant, since Mr. McDonald would hardly consent to take charge of a property that did not possess future promise.

Herbert Creek—Dolan & Pinkert have confirmed their good judgment in the purchase of the upper thousand feet of discovery on Herbert creek, several shafts disclosing pay dirt of exceptional value.

YUKON TERRITORY—WHITE HORSE

Work has been stopp'd on the spur from the White Pass Railway to the copper mines near White Horse with only one-half of the track laid. Resumption of this work will depend upon the intentions of the mineowners. The railway company can finish the extension in six weeks time.

Mexico

CHIHUAHUA

Candelaria—These old mines are now shipping at the rate of 150 to 200 carloads monthly to the El Paso plant of the American Smelting and Refining Company. The working force numbers about 600. The new pumping plant is handling about 3000 gal. of water per minute and keeps the old workings sufficiently dry to permit of ore extraction in the lower levels and for the sinking of deeper shafts. George A. Laird is in charge.

Mary Mining Company—This company, operating in the Archuayo district in the western part of this State, has the necessary machinery on the ground for a to-stamp mill. The property is best reached from Alamos, Sonora. E. McLean is the superintendent.

Santa Indaba Development Company—An English company, represented by I. M. Cockerell, has a purchase option on the Samambulo and Nueva Chihuahua mines in the Santa Eulalia camp and will begin immediate development.

San Carlos—This company is making surveys for a railroad to its property in the San Carlos section, in the northern part of the State. One line as projected is to be built from the Southern Pacific

at either Boquillas or Sanderson, Texas; the other is to run to the Orient railroad in eastern Chihuahua. Dr. C. V. F. Caracristi is general manager.

Urique—It is reported that transfer of the Santa Reyes and Trumbo mines near Urique, has been made to John Paul and Dr. Sheldon, representing New York parties.

Waterson Gold—Among the late bullion shipments received at the local bank is one of nine bars of gold-silver from this company, valued at 19,000 pesos.

DURANGO

La Luz—Daniel E. Webster is making a topographic survey of this and the Santa Inez Mining property for the owners W. R. Giesecke and associates of Gomez Palcio.

Cinco de Mayo—The new shaft has been completed to the water level and obtained an abundant supply of water. With this water available, the work of extracting the ore from the upper workings will begin. It is reported that a rich body of copper ore was recently cut at a depth of 320 feet.

Guanacevi Tunnel Company—At Guanacevi, Durango, the company is receiving bids on an electric equipment for the driving of a development-transportation tunnel 12,000 ft. long. A. D. Meloy, of New York is chief promoter of this enterprise.

GUANAJUATO

Santa Natalia—The first shipment of bullion was made from this mine recently.

Africa

WEST AFRICA

Gold production of the Gold Coast and Dahomey is reported by the West African Chamber of Mines at 21,491 oz. in April, being 1795 oz. less than in March. For the four months ended April 30 the total was 102,032 oz. bullion in 1908, and 88,897 oz. in 1909; a decrease of 13,135 oz. The bullion reported this year was equal to \$1,746,885, or 84,513 oz. fine gold.

South America

BRITISH GUIANA

Gold exports for the four months ended April 30 were 17,627 oz. bullion in 1908, and 18,385 oz. in 1909; an increase of 758 oz. The bullion reported this year was equal to \$317,955, or 15,373 oz. fine gold.

Exports of diamonds for the four months were 537 carats, valued at \$3246; an increase of 149 carats over last year.

Guiana Gold Company—The large new gold dredge built by this company on the Conawarook river sank just after it had been completed, and the day before it was expected to begin work. Faulty construction is suspected to be the cause.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, June 2.—From the West reports come of an improvement in the demand for steam coal which is growing much faster than it has been for some time past. So far this improvement has not been generally accompanied by any advance in prices, mainly for the reason that producers have been rather too anxious to take advantage of any gain, and have shipped coal to the central market points too freely. Consumption is increasing, however, and the complaints of iron and steel sales to avoid demurrage are not very serious.

In the East improvement in the bituminous trade seems to be much slower than in the West, and a good many complaints are still heard of slow purchasing of coal. That there is some improvement, however, is not denied.

The anthracite trade is steady and rather quiet; many collieries are still running on short time and may continue to do so for another month before accumulated stocks are worked off.

Lake Coal Rates.—In Charleston, W. Va., May 27, Judge Keller, of the United States Circuit Court, dissolved the temporary injunction issued by him last April restraining the Kanawha & Michigan, the Chesapeake & Ohio and Norfolk & Western railroads from filing with the Interstate Commerce Commission a proposed tariff increasing the rates on local shipments of coal from West Virginia fields to the lake regions on the ground of lack of jurisdiction. In the case of the Columbus Iron and Steel Company against the Kanawha & Michigan railroad to prevent the filing of the tariff the Court held it had no right to prevent filing before the Interstate Commerce Commission had determined equity of rate. Similar injunctions in the case of the Imperial Colliery Company versus the Chesapeake & Ohio Railroad and the Powhattan Coal & Coke Railway versus the Norfolk & Western were dissolved. This permits the new rates on Lake coal to go into effect.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, say to May 22 short tons:

	1908.	1909.	Change.
Anthracite	2,177,732	2,301,826	D. 75,996
Bituminous	12,690,625	13,650,697	1,110,972
Coke	2,698,396	3,874,226	1,175,831
Total	17,566,753	19,826,749	2,259,997

Increase for the week, 91,050 tons. Total increase this year to date, 12.5 per cent.

New York

ANTHRACITE

June 2.—There was a little sport in the market last week brought about by parties who wanted to get in orders on the May discount. It did not amount to very much, however, and trade generally has been quiet but rather steady. On June 1 another 10c. was taken off the discount and prices for prepared sizes are now \$4.45 for lump, and \$4.70 for egg, stove and chestnut, all f.o.b. New York harbor. For steam sizes current quotations are unchanged at \$3.10@3.25 for pea, \$2.35@2.50 for buckwheat, \$1.70@2 for rice or buckwheat No. 2, and \$1.25@1.50 for barley, f.o.b. New York harbor points.

BITUMINOUS

The Seaboard trade grows slowly, although some advance is perceptible. Taking of coal under contracts is the principal improvement noted. The far East is reported to be thinking about sending in orders, but has hardly got to the point of action. The Sound is doing a little better, and all-rail trade better yet. New York harbor is quiet. Some coal continues to change hands at rather low prices; otherwise there is not much movement.

Coastwise trade is fair, but not as active as it might be. Vessels being in good supply, rates are unchanged.

Birmingham

May 31.—The coal trade in Alabama shows little improvement. Some price cutting has been going on, but this has not included any great amount of business. A large number of miners are out of employment and those who are working are not getting in steady time. The coke demand continues good. The annual convention of the United Mine Workers of America, Alabama district No. 20, will be held in Birmingham, June 14. The attendance promises to be small as the union has not been doing much since the strike last year.

Chicago

June 1.—While the consumption of steam coals is increasing, the shipments to this market of Illinois and Eastern lump are so large that a good deal of price cutting, due to demurrage regulations, again exists. Fine coals, on the con-

trary, are comparatively scarce and are advancing slowly. Springfield screenings, a favorite summer fuel, bring \$1.45 readily and other screenings from Illinois and Indiana mines sell for \$1.55@1.75. Run-of-mine remains at \$1.65@1.75, and lump finds purchasers, with difficulty, at \$1.75@2.25, these being car prices. Domestic bituminous coals are hardly in the market, sales being very light.

Contract making has been brisk and a larger volume of coal has been sold on contracts than a year ago. But prices are very low on most of this business and the open market seems to have a brighter outlook.

Eastern coals are selling well, but smokeless run-of-mine and Hocking are off to or 15c from list prices because of demurrage. The best smokeless and Hocking, however, hold up well to list quotations. Youghiogheny 34-in gas brings \$3.15, with a steady market; Pittsburgh No. 8 is in similar shape at \$2.65 for 34-in. Anthracite finds a light but steady sale, well distributed.

Cleveland

June 1.—The local coal trade is improving and sales are better than they have been. Mills and factories are taking more steam coal. Prices are strengthening, though some coal has been sold low, to avoid demurrage. No. 8 district brings about \$1.00@2.05, Cleveland, for lump; \$1.80 for run-of-mine and \$1.35@1.40 for slack. Middle District coal sells at \$1.80@1.95 for lump, \$1.70 for run-of-mine and \$1.30@1.35 for slack, all Cleveland.

Lake trade is so slow yet that the railroads are putting an embargo on shipments from mines, the yards being full of coal waiting for vessels up the Lakes.

Indianapolis

May 31.—A general review of the coal-mining and market situations shows a decided improvement over the previous week. Operators say that progress is slow, but constant, and with the reported revival in iron and steel industries justifies a hopeful outlook. That more optimism is being shown is evidenced by the opening of several mines during the past week that have been closed from one to two years.

The activity among retail dealers in buying their storage supply which set in the last few days has been encouraging.

The decreasing number of empty cars reflects the increasing run of summer orders. Operators, however, do not believe that conditions will justify anything above a conservative advance in prices at present.

Pittsburg

June 1.—The coal market continues quiet, with continued price cutting. Nominal prices remain at \$1.10 to manufacturers and \$1.20 to retail dealers, for mine-run at mines, but these prices are being shaded 5 to 10 cents a ton as formerly. Slack is quotable at 60 to 95 cents.

Connellsville Coke—The chief topic of conversation in the trade is the merger. The promoters insist that it will be put through and will be able to make fair profits, but the trade at large figures by various methods that it cannot possibly be a success, on account of the high prices asked for the properties, these prices being held to be such that nearly a dollar a ton would have to be earned to carry interest and exhaustion charges, pointing to \$2.35@2.50 for coke. In view of the many other sources of supply it is maintained that such prices cannot be obtained.

The Thompson Connellsville Coke Company has made a contract to supply the Jones & Laughlin Steel Company with 400,000 tons of coke a year for a period of time, believed to be three years from Sept. 1 next. A flat price is to be paid, which is somewhat unusual in such cases. While the price is not stated authoritatively, it is believed in some quarters to be about \$2 at ovens.

The coke market is a trifle firmer for prompt coke, \$1.50@1.60 being demanded for prompt furnace, second half-contracts remaining at \$1.60@1.80, according to grade. Foundry coke is \$1.50@2 for prompt and \$1.90@2.25 for contract, depending on grade.

The *Courier* notes a gain of 10,000 tons in production in the Connellsville regions in the week ended May 22 as compared with the preceding week, the output being given at 278,720 tons. Shipments are reported at 3296 cars to the Pittsburg district 5433 cars to points west of Pittsburg and 742 cars to points east of Connellsville; a total of 9471 cars a gain of 100 cars.

Foreign Coal Trade

United States Coal Exports—Exports of coal and coke from the United States, four months ended April 30, long tons:

	1908.	1909.	Change.
Anthracite.....	703,018	699,350	D. 3,668
Bituminous.....	2,350,186	2,072,696	D. 277,490
Total coal.....	3,053,204	2,772,046	D. 281,158
Coke.....	258,242	330,370	I. 72,128

Canada took this year 1,991,594 tons, or 71.8 per cent. of the total coal. The coke went chiefly to Mexico and Canada.

United States Coal Imports—Imports of coal and coke into the United States, four months ended April 30, long tons:

	1908.	1909.	Changes.
Anthracite.....	15,923	3,115	D. 12,808
Bituminous.....	404,342	388,077	D. 216,065
Total coal.....	619,165	391,192	D. 227,973
Coke.....	41,444	64,186	I. 22,742

Canada sent this year 330,926 tons of coal and nearly all the coke; Australia, 41,048 tons of coal. Imports are chiefly on the Pacific coast and on the northern border, into Montana and Washington.

Imports of coal into Spain in January were 172,860 metric tons, an increase of 33,073 tons; of coke, 25,757 tons, an increase of 10,151 tons.

Nova Scotia Coal—Coal shipments from Nova Scotia mines, four months ended April 30, long tons:

	1908.	1909.	Changes.
Domestic.....	778,291	549,632	D. 228,659
Nova Scotia Steel ..	158,746	112,141	D. 43,605
Cumberland.....	144,528	124,355	D. 20,173
Acadia.....	106,421	75,831	D. 30,590
Intermar.....	68,601	48,957	D. 19,734
Intercolonial.....	90,055	80,139	D. 9,916
Total.....	1,345,732	991,055	D. 352,677

The total decrease this year to date was 20.2 per cent. In the March statement, recently published, the figures for 1908 and 1909 were accidentally reversed.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on May 22: Best Welsh steam, \$4.02; seconds, \$3.84; thirds, \$3.60; dry coals, \$3.84; best Monmouthshire, \$3.48; seconds, \$3.30; best small steam, \$2.04; seconds, \$2.40. All per long ton, l.o.b. shipping port. This is an advance on Welsh coals.

Iron Trade Review

New York, June 2—There are signs of a slight lull in buying following the extreme activity which the iron and steel trades showed in the latter part of May. It does not appear that this will be a serious check, but rather a pause to take stock and see what has been done. The effect of the recent activity has been to fill most of the mills with work for at least three months to come and put buyers in a position to supply the actual and expected demands from consumers. Some slight advances in price have been made, but the great bulk of the business placed has been at the lowest figures.

In pig iron basic sales continue active and a good deal is still being done in foundry iron. Furnaces in blast are increasing in number, especially those owned by the steel companies. A few of the latter have been buying bessemer pig iron from outside furnaces, which has not been done for over a year and a half. The merchant furnaces are consequently selling iron on prices, not making advances for immediate deliveries, but making no concessions and looking for 25 or 50c

more for third- and fourth-quarter deliveries.

Running parallel with the demand for basic iron has been an increased demand for scrap. This has been felt to some extent in foundry scrap, but in a much greater degree in the call for heavy steel melting scrap which is beginning to be rather scarce.

In finished material, structural steel is still in the lead, but large business has been placed in plates, sheets and bars. The railroads are still holding back on rails, although small orders are coming in more freely, and there is quite a market for light rails. The railroads have been ordering a good number of steel cars and are also asking bids for many locomotives.

Tinplate Capacity—It is announced that the Jones & Laughlin Steel Company, in addition to other improvements, will build a tinplate mill of large capacity, entering into active competition with the American Sheet and Tin Plate Company.

Baltimore

June 1.—Exports for the week included 1,306,731 lb. tin-scrap to Rotterdam; 2894 tons rails and 100 tons rail fastenings to Buenos Aires; 3853 tons rails and 200 tons rail fastenings to Mexico. Imports included 4525 tons iron pyrites from Spain; 16,450 tons iron ore from Cuba.

Birmingham

May 31.—Southern pig iron manufacturers are encouraged over the steady inquiry that is being received; some orders are developing. Some selling is still going on and the quotations are strengthening. Third-quarter iron being held firmly for \$11.50 per ton, No. 2 foundry, and fourth-quarter iron at \$12. Reports are still current that one or two companies are inclined toward a lower price, and that \$11 is being accepted for June and July deliveries. There is a quantity of iron to be seen in furnace yards, but the statement is that it awaits instructions as to delivery. The foundrymen and machine shop proprietors in this section of the country have recently been receiving a number of orders and their business is better. Some bidding is going on also on machinery orders. The blowing out of two furnaces this month will be followed by the blowing in of two others in the next few days. It is expected also that within a month the Southern Steel and Iron Company, successor to the Southern Steel Company, will have started preparations looking to a resumption of operations at three blast furnaces, the steel plant at Gadsden and the mills at Ensley. W. H. Hassinger, of Birmingham, was elected president of the reorganized company. Rumors prevail that the Tennessee company will add a structural-steel department to the steel plant at Ensley.

This plant is still idle. The Bessemer rolling mills will resume operations this week after a month's idleness.

Chicago

May 31—Quiet exists in the pig-iron market. The situation has been forecasted in the gradual slackening of the last month or six weeks; it seems due to the fact that foundries in this territory are well provided with iron, up to the last quarter at least, and their proprietors have decided again to go slowly. For needs of the third and fourth quarters the standard purchase remains small—under 500 tons. The selling price of Southern remains nominally \$11.50 Birmingham (\$15.85 Chicago), but \$11.25 and even \$11 is done on some business. Northern is quoted at \$16.50, but can be had in any good-sized quantity at 25 or 50c. less. With both sellers and buyers watching the market keenly, any decided change stiffening the market will result in comparatively heavy buying, but no such change seems imminent.

In the iron and steel products market conditions continue good, especially in structural material and railroad supplies, and with no notable falling off in any line. Coke is improving as to sales and holds to \$4.70 for the best Connellsville.

Cleveland

June 1—Buying of iron ore continues at a fair rate. So far as shipments are concerned, the strike is causing trouble, but not enough to stop boats, or to prevent the movement of ore.

Pig Iron—The sales are steady, but not in large lots. Prices have not been advanced, but are more firmly held, the basis continuing about \$15.25, Cleveland, for No. 2 foundry.

Finished Material—Structural steel is in demand still. In other lines the market is quieter, owing chiefly to the recent heavy sales. The mills are busy and buyers are supplied for the present.

Philadelphia

June 2—A stronger tone exists in the pig-iron market. The large buyers of foundry iron have covered their requirements for the most part, but the firming up of prices has brought out many orders from small people, who would not buy before. Prices are a step higher, No. 2X bringing \$16.25@16.50, while many sellers ask 25c more for third quarter and 50c for fourth-quarter iron. A large movement in basic still continues. Alabama iron is not much in evidence, but Virginia furnaces are getting some business. Forge iron is looking up.

Steel Billets Business is chiefly in small lots. Sellers are stiffer in their prices.

Scrap—Prices seem to be advancing, and dealers are not pressing sales, believing that they will do better by holding back. Heavy steel-melting scrap is in demand.

Pittsburg

June 1—The general iron and steel market has become quieter since last report. While there has been no loss in prices there has been a slight loss as to activity. It has become clearer that the buying of finished steel products in the past three months represented a distinct movement, and not the establishment of a rate which would be followed indefinitely. Buyers provided for their known requirements for some distance ahead, while there was a large tonnage bought to be placed in stock, as in many instances the lowest prices were not made unless the buyer would obligate himself to take out a given tonnage by July 1. Thus a heavy pressure is brought upon the mills for the time being. The current rate of production is probably considerably in excess of consumption, this excess going into stocks of jobbers and manufacturers, which were very low.

Pig Iron—The market has been quieter since the advances noted in last report. Buyers seem to be well covered to July 1, while those who have not bought for third quarter seem to be in no hurry to do so. Stocks of unsold iron are large, being estimated by a prominent buyer last week at 1,300,000 tons, of which there are probably 150,000 tons in Alabama and 250,000 tons in Virginia, leaving 900,000 tons for the northern districts. No effort is being made to dispose of these stocks, but should the holders suddenly conclude to liquidate prices would naturally suffer. The market at present is firm. Standard Bessemer is firm at a minimum of \$15. Valley, for any delivery, some sellers quoting \$15.25@15.50. Basic is quoted by a few sellers at \$14.50. Valley, for second half delivery, the majority quoting \$14.75, while for prompt iron \$14.35 has been done, and this price could possibly be duplicated. Foundry iron is \$14.50@14.75. Valley, sales having been made at both prices. Malleable is quoted at \$14.50@14.75. Valley, and forge at \$13.50@13.75. Valley, the freight to Pittsburg being 90c.

Steel—A sale of 100 tons of sheet-bars for June delivery has been made by a local steel producer to a local tin mill. It is reported that a local steel interest has sold a supply of sheet-bars to a prominent independent tinplate interest for delivery over the second half at a price below the recognized market, which is \$25.50. delivered. Billets remain at \$23, Pittsburg, with light transactions. Bessemer rods are \$20, f.o.b. Pittsburg, and open-hearth \$20. Deliveries of plates have improved further. The Pressed Steel Car Company and Standard Steel Car Company are now running at fully half their capacity, and

with orders on books will be able to maintain this rate for several months. Plates are firm at 1.30c, Pittsburg, except that this basis is shaded occasionally in the case of large structural contracts.

Sheets—If anything, the market is a trifle weaker, although tonnage is as good as it was. The regular market is 2.20c. on black and 3.20c. on galvanized, on attractive orders, but in special cases these prices are sometimes shaded an extra \$1 per ton.

Ferromanganese—The market is quiet. The regular quotation is \$41, Baltimore, or \$42.95, Pittsburg, but occasionally this price is shaded.

Metal Markets

New York, June 2—The metal markets continue to improve and there is increased buying by manufacturers in almost all lines. Confidence seems to be felt in the future, orders being placed for some time ahead.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
April 1909...	\$ 3,349,307	\$ 6,337,994	Exp. \$ 2,988,687

" 1908...	17,048,851	14,298,582	2,750,269

Exports from the port of New York, week ended May 29: Gold, \$300,000, chiefly to London. Argentina: silver, \$403,525, chiefly to London. Imports: Gold, \$124,034; silver, \$80,434, both principally from Central and South America.

Gold and silver movement in Great Britain, four months ended April 30:

	Imports.	Exports.	Excess.
Gold.....	£20,878,859	£14,472,570	Imp. £6,406,280
Gold, 1908...	16,824,776	11,455,953	Imp. 5,368,823
Silver.....	4,202,376	4,321,269	Exp. 118,893
Silver, 1908...	3,408,028	4,579,870	Exp. 1,171,842

Of the silver imported this year £3,574,425 came from the United States.

Gold and silver movement in France, three months ended March 31:

	Imports.	Exports.	Excess.
Gold..Fr.	165,570,000	Fr. 23,020,000	Imp. Fr. 142,550,000
1908..	150,009,000	7,869,000	Imp. 142,141,000
Silver...	36,557,000	30,309,000	Imp. 6,248,000
1908...	31,120,000	43,515,000	Exp. 12,395,000

Imports of copper and nickel coins, 18,000 fr. in 1908, and 10,000 fr. in 1909; exports, 90,000 fr. in 1908, and 75,000 fr. this year.

Gold—There was no special demand for gold in the open market in London this week, and the prices continued unchanged at 77s. 6d. per oz. for bars and 70s. 10d. per oz. for American coin. Most of the gold was taken by the Bank of England, and for Austrian account. In New York \$1,250,000 was taken today for shipment to Buenos Aires.

Platinum—Business has been rather slow, as is usual at this season. Prices are about 50c. lower, dealers quoting \$22.50@23 for refined platinum, \$25 for hard metal and \$18@20 for scrap.

Silver—The market continues very steady, and indications point to small fluctuations for the present.

SILVER AND STERLING EXCHANGE						
May-June,	27	28	29	31	1	2
New York....	52½	52½	53		53	52½

Total.....	£ 3,689,918	£3,096,200	D. £ 593,718

Imports for the week, £2000 from Chile, £7000 from the West Indies, £4000 from Mexico, £159,500 from New York; total, £172,500. Exports, £385,000 to India.

Copper, Tin, Lead and Zinc

May-June.	Copper.			Tin.	Lead.		Zinc.
	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per ton.		New York, Cts. per lb.	St. Louis, Cts. per lb.	
27	13½	13½	61	29½	4.30	4.25	5.07½
28	13½	13½	61	29½	4.35	4.30	5.10
29	13½	13½	60½	29	4.35	4.30	5.12½
30	13½	13½		29	4.35	4.25	5.07½
31	13½	13½		29	4.35	4.30	5.12½
1	13½	13½	60½	29½	4.35	4.25	5.10
2	13½	13½	60	29½	4.35	4.30	5.12½

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations for spelter are for ordinary Western brands; special brands command a premium.

Copper—While business continued very active and transactions were numerous and on a large scale during the early part of the week, the market has quieted down since prices were raised on June 1. The market closed steady at 13½@13½c. for Lake copper; 13½@13½c. for electrolytic in ingots, cakes and wirebars. The average for casting copper during the week was 13@13½ cents.

Copper sheets are 17c. base for large lots. Full extras are charged, and higher prices for smaller quantities. Copper wire has been advanced ½c. to 14½c. base, car-load lots at mill. Business is good.

The standard market in London held firm until Tuesday, when a realizing movement of large proportions set in with the publication of an increase in statistics of 5,400 tons. The close is lower and easy at £60 for spot, and £60 16s. 3d. for three months.

For refined and manufactured sorts we quote: English tough, £64; best selected, £63@64; strong sheets, £75@77.

At the beginning of May copper was on the basis of 13c. for Lake and 12½@12½c. for electrolytic. The important demand that developed at the end of April expanded during the first half of May and transactions became extraordinarily large. The volume of business was somewhat smaller during the second half of May, but continued large. The total sales for the month were very much in excess of the production. However, it is to be remarked that they covered deliveries extending several months ahead. At the beginning of May sellers were willing to make contracts for August delivery and some such transactions were made, but when the demand increased in strength the agencies generally refused to make contracts for later than July, except at an advance in price corresponding to carrying charges. At the end of May, however, some sales were being made for August delivery. The demand from domestic consumers improved very much during the month but at the end it appeared to be more or less satisfied, sales for near-by delivery being effected rather slowly. A large part of the transactions in May were speculative, there having been a rampant bull movement in the London market, emanating largely for this side. The superior advantages of speculating in copper, as compared with shares in the companies, was extensively urged. This speculation was a reminder of that which occurred last fall, when many outsiders took an interest in the market. Under these influences the price for standard copper in London was bid up above the parity of refined, and of course, the international houses took advantage of the opportunity to sell standard and deliver refined against their sales. As in the former case this implies an element of danger in the London market. At the best it indicates merely a transfer of a part of the accumulated stock. Indeed the European statistics at the end of May show an increase in the supply, while the American statistics, it is anticipated, will show a decrease. In the New York market there was a steady advance in price during May and at the close Lake copper was 13½c. and electrolytic 13 13/16 cents.

Exports of copper from the United States, four months ended April 30, are reported by the Bureau of Statistics at 88,340 long tons; this includes estimated contents of ore and matte, which were comparatively a small quantity. Exports for May are estimated at 31,423 tons,

making a total of 120,363 tons for the five months.

Tin—The market in London remained very quiet. The only feature of interest which developed was the favorable statistics for the month of May which were published on June 1. The effect on quotations, however, was only minimum, and the small advance could not even be maintained. The market closes steady at £131 17s. 6d. for spot and £133 2s. 6d. for three months.

The domestic market moved in sympathy with the London market, attaining its high point on the first of the month, but closes somewhat easier at about 29½ cents.

Lead—The market is firm and the leading sellers have again advanced their price to the extent of \$1 a ton, thus making the quotation at New York 4.35, while St. Louis is quoted at 4.25@4.30. Chemical lead has sold at St. Louis as high as 4.32½ cents.

The John Wahl Commission Company telegraphs us from St. Louis, under date of June 2, that lead is strong at the advance. Missouri brands are selling at 4.32½@4.35c. basis, East St. Louis.

The London market is again somewhat lower, the close being cabled at £13 2s. 6d. for Spanish and £13 5s. for English lead.

Spelter—The improvement in the steel and iron industry continues to exercise a favorable influence upon the price of spelter, and under the impetus of a good business, the market advanced to 5.10@5.12½c., St. Louis, 5.22½@5.27½c., New York.

The London market is firm, and the close is higher at £22 2s. 6d. for good ordinaries, £22 7s. 6d. for specials.

The John Wahl Commission Company telegraphs us from St. Louis, under date of June 2, that the latest sales of spelter have been on a basis of 5.15c., East St. Louis.

New York quotations for spelter, May 27, were 5.22½@5.25c.; May 28 and 29, 5.22½@5.27½c.; June 1 and 2, 5.25@5.27½ cents.

Base price of sheet zinc is 6¼c. per lb., i.e. La Salle-Pern, less 8 per cent. discount.

Other Metals

Antimony—The market has been dull. In the absence of large sales quotations are unchanged at 8½c. for Cookson's; 7½c. for U. S. and 7¼@7½c. for outside brands.

Aluminum—Business is fair; otherwise there is no change. Prices are 22@24c. base for No. 1 ingots; 31@32c. base for wire; 33@34c. base for sheets.

Quicksilver—Business has been better, but New York prices are unchanged at \$44.50 per flask of 75 lb. San Francisco, \$44 for domestic orders and \$42 for export. London price is £8 7s. 6d. per flask, but 5s. lower is quoted from second hands.

Nickel—Large lots, contract business, 40¢ a 50¢ per lb. Retail, spot, from 50¢. for 2000-lb. lots up to 55¢. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots, for 5-lb. lots, \$1.40 per pound.

Imports and Exports of Metals

Exports and imports of metals in the United States, four months ended April 30, are reported as follows, in the measures usual in the trade:

Metals:	Exports.	Imports.	Excess.
Copper, long tons.....	88,940	48,577	Exp. 40,363
Copper, 1908.....	124,406	27,219	Exp. 97,187
Tin, long tons.....	229	14,332	Imp. 14,103
Tin, 1908.....	109	16,518	Imp. 16,409
Lead, short tons.....	31,592	34,398	Imp. 2,806
Lead, 1908.....	26,892	37,768	Imp. 10,876

 Chrome ore, 1908, ... 15,272 Imp. 15,272
 Chrome ore, '08
 Copper, lead and nickel include the metal contents of ores, matte, bullion, etc. The exports given include reexports of foreign material. Imports of zinc ores in 1909 included 21,230 tons calamine and 10,315 tons other ores, against 5103 and 5796 tons, respectively, in 1908. Chrome ore was not reported separately last year.

Zinc and Lead Ore Markets

Afternoon, Wis., May 29—The highest price paid this week for zinc ore was \$43; the base price, \$10.50¢ a \$1 per ton of 60 per cent zinc. For 80 per cent, lead ore, \$55.00/\$56 per ton was paid.

SHIPMENTS, WEEK ENDED MAY 29

Total.....	4,840,775		409,000
Year to May 29.....	17,239,729	1,950,035	3,916,000

Highland, Under, Barker are not reported. In addition to the above there

was shipped to the American Zinc Ore Separating Company, 90,100 lb., and to the Joplin Separator Works, 409,000 lb. zinc concentrates.

There was shipped in the previous week, not then reported, from Highland, 65,800, from Linden, 56,220, from Barker, 77,750 and from Montfort, 40,000 lb. zinc ore; from Highland, 54,600 lb. lead ore.

Joplin, Mo., May 29—A sharp competitive market has advanced prices to \$46 per ton for the highest grade of zinc sulphide ore. Offerings of \$43.50 base were numerous, and ore is reported sold on flat bids at a price equivalent to a base of \$44 per ton of 60 per cent zinc. The base price for slimes, or sludge ore, was \$38. Silicate of zinc ore sold on a base of \$17 to 19.50 per ton of 40 per cent zinc, the highest sale being at \$25.50. The average price, all grades, was \$39.30. The high price for lead ore was \$50, with medium grades selling at \$57 to \$58. The average price, all grades, was \$57.80 per ton.

The zinc-ore market has been in a nervous and excitable condition all this month, and all efforts to establish any semblance of unity of price offerings by smelters, or of acceptance terms by sellers, have proved futile. For three weeks buyers

SHIPMENTS, WEEK ENDED MAY 29.

Year.....	\$36.43		\$31.31		\$53.93	

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

have made purchases varying from \$1 to \$2 per ton for the same grade of ore. Instead of anticipating the advance sellers have been as greatly at sea as buyers.

Chemicals

Veterinary, June 2—Current demand in most lines is for moderate sized lots. Heavy shipments are restricted chiefly to contract business.

Copper Sulphate—Sales are better and prices a little firmer. Quotations are, \$1.25 per 100 lb. for carload lots, and \$4.50 per 100 lb. for smaller orders.

Arsenic—Sales have been fair and quotations are a little higher, 2½¢@3c. being asked for white arsenic.

Nitrate of Soda—The market is good with many sales. Spot nitrate is steady at 2.25¢; futures are a shade lower, at 2.12½¢, in view of good supplies reported afloat.

Imports and Exports—The imports and exports of chemicals and raw materials in the United States, four months ended April 30, were as follows:

	Imports.	Exports.	Excess.
Copper sulph. lb.....	1,873,866	E. 1,873,866	
Blanch, lb.....	30,017,652	E. 5,152	1. 30,022,804
Potash salts, lb., 133,858.84	1,374,219	E. 1,321,811	1. 52,408
Soda salts, lb., 4,726,522	237,378	E. 4,489,144	1. 4,489,144
Acetic lime, lb.....	32,085,786	E. 32,085,786	
Nit. of soda, tons.....	117,662	E. 2,709	1. 113,859
Phosphates, tons.....	3,997	E. 340,206	1. 336,209
Sulphur, tons.....	9,931	E. 9,920	1. 11
Pyrites, tons.....	223,768		1. 223,768

Exports include reexports of foreign material. Estimating sulphur contents of pyrites, the total sulphur imported was approximately 90,124 long tons.

Mining Stocks

Afternoon, June 2—After a holiday extending from Friday over to Tuesday the Stock Exchange opened rather strong and prices were well held on a good volume of trading. The most notable feature in the market continues to be the strength of Steel Corporation stocks, especially the common, which has advanced steadily and holds at a new record price. It is thought by many that this is an inside movement, but its object is not clearly apparent. Matters on the Exchange look very much as if preparations were being made for a strong bull movement.

On the Curb also there was an active market, but the movement was rather mixed, some stocks going over last week and others losing. Copper shares were in good demand and showed considerable buying, especially Nevada Consolidated and Cornwell & Co., while Ray Consolidated made a fair advance. In the Nevada stocks Goldfield Consolidated was heavily dealt in and some other stocks showed considerable strength. Some attention was also given to the Cobalt stocks, La Rose and Nipissing being the

leaders. There was some sales of Yukon Gold, but little change in price.

Boston, June 1.—The week covers but four days of stock market, as the Saturday preceding and the Monday following May 30 were market holidays. Prices, however, have shown a gradual hardening tendency, and commission houses report increased business, which indicates that the public is taking an interest. The ease of money is a contributing cause, although there is room for improvement, market-wise.

Mass mining has been the feature, showing an extreme advance of \$3.87 to \$18.25, but today it broke to close to \$14 on selling from the Lake Superior district. Stop orders were reached which facilitated the decline. It seems that a mill-run test is being made on the recent strike of rich ore and precedent has established the rule that it is a good time to realize profits.

North Butte has been less of a market factor and selling pressure has been removed, for the time being at least. After stiffening \$2.75 to \$50, it fell back to \$56.75 again. Calumet & Hecla is up \$40 for the week to \$675 per share, which cannot be construed any other way than favorable. Copper Range has been dull, although it showed animation today up to \$82.25 on declaration of the usual quarterly dividend of \$1 per share.

The Curb market has been principally in stocks that will sooner or later be taken over on the Stock Exchange list. As a rule, it has been firm in tone.

THE MINING INDEX

The editors of this paper read all the important publications of the world that relate to mining and the treatment of minerals. This index is published as a reference for all interested and to make it impossible for readers of the **ENGINEERING AND MINING JOURNAL** to miss any important article published anywhere.

We will undertake to furnish a copy of any article (if in print) in the original language, for the price quoted. Where no price is quoted the cost is unknown. These papers are not kept in stock, but must be ordered from the publisher; hence there will be some delay for foreign papers.

No accounts can be opened for these small amounts, but remittance must be sent with order. For the convenience of those making small but frequent remittances, coupons are furnished at the following prices: 20 cents each, six for \$1.00, thirty-three for \$5.00 and one hundred for \$15.00. This arrangement will be especially appreciated by foreign readers and men in distant mining camps. Where remittances are made in even dollars we will return the excess over an order in coupons upon request.

ALUMINUM

9365—**WELDING**—Aluminum Welding. M. U. Schoop. (Electronics and Met. Ind., May, 1909; 2 pp.) Notes on the applications of aluminum welding and description of the most suitable type of burner. Illustrated. 40c.

ANTIMONY

9366—**METALLURGY AND USES OF** Antimony. E. B. Wilson. (Mines and Minerals, May, 1909; 2 pp.) Notes on the use of antimony; its ores, methods of testing; wet and dry assays and metallurgical processes. 20c.

ASBESTOS

9367—**QUEBEC ASBESTOS**—World's Supply Controlled. Alex Gray. (Min. Journ., Apr. 5, 1909; 1 p.) Statistics on the asbestos industry in Canada; the names of the companies in the asbestos neighborhood, together with notes on prices and markets. 40c.

ASPHALTUM

9368—**GRAHAMITE DEPOSITS** of Southeastern Oklahoma. Joseph A. Taff. (Bull. No. 380-H, U. S. Geol. Surv., 1909; 12 pp.) Notes on the location and occurrence of grahamite in southeastern Oklahoma, together with a review of the geology of the district.

9369—**NEVADA**—An Occurrence of Asphaltite in Northwestern Nevada. Robert Anderson. (Bull. No. 380-H, U. S. Geol. Surv., 1909; 3 pp.) Some notes on the occurrence and character of asphaltite as found in Northwestern Nevada.

9370—**WEST AFRICA**—Bitumen and Oils in West Africa. T. Hugh Hoorman. (Eng. and Min. Journ., May 22, 1909; 1 p.) A brief report on the occurrence of bitumen at Nigeria with analyses in which it is compared with that of Trinidad and Bermudez. 20c.

BORAX

9371—**CALIFORNIA**—Borate Deposits of California. Wilfred B. Walnwright. (Trans. Manchester Geol. and Min. Soc., Part IV, Vol. XXXI, 1909; 7 pp.) A short description of the mineral deposits, together with notes on the refining of crude borax.

CALCIUM CARBIDE

9372—**MANUFACTURE OF** Calcium Carbide. (Engineering, Apr. 2, 9, 16 and May 7, 1909, 8 pp.) Continuation of article previously indexed, describing the installation and operation of the electric generating plant, and general arrangement of the works at Udny. Also gives details of the carbide way used in handling raw material, the carbide furnaces, crushing machinery and the manufacture of drums and barrels for the finished product. \$1.40.

CEMENT

9373—**COLORADO**—The Niobrara Limestone of Northern Colorado, as a Possible Source of Portland Cement Material. C. C. Martin. (Bull. No. 280-J, U. S. Geol. Surv., 1909; 13 pp.) Notes on the general geologic features of the district; requirements for cement materials; a description of the material occurring near Ft. Collins, Colorado, together with analyses of cement rock.

9374—**COMPOSITION AND CHARACTERISTICS OF** Cement. Alfred E. Corder. (Min. Sci., Apr. 8, 1909; 2 pp.) Some notes on the history, advancement, uses and various forms of cement. Illustrated. 20c.

9375—**MONTANA**—Cement Material Near Havre, Mont. Leon J. Pepperberg. (Bull. No. 280-J, U. S. Geol. Surv., 1909; 9 pp.) Notes on the geology of the district and composition of cement materials. Also notes on the economic conditions.

9376—**PORTLAND CEMENT**. John L. Howard. (Min. and Sel. Press, May 1, 1909; 4½ pp.) An historical review of the cement industry, together with notes on tests for soundness, fineness, tensile strength and compressive strength. 20c.

9377—**TESTING**—Standard Methods of Testing Cement. Carney Hartley. (Min. Sci., May 13, 1909; 3 pp.) An article dealing with the importance of a proper test of the cement prior to use, giving specifications for cement and the method of determining quality. Illustrated. 20c.

CLAYS

9378—**FLORIDA**—Notes on the Clays of Florida. George C. Matson. (Bull. No. 380-K, U. S. Geol. Surv., 1909; 24 pp.) A description of the clays of different geologic periods together with a number of chemical analyses. Also a description of the mining method and manufacturing processes.

COAL AND COKE

9379—**ALBERTA**—Coal Mining in Alberta During the Year 1908. (Can. Min. Journ., May 15, 1909; 3½ pp.) A review of the coal industry in Alberta during 1908; the development of old mines and the opening of new ones, and the names of the principal operating companies. Illustrated. 20c.

9380—**ANALYSIS OF THE SUBJECT OF** Coal Analysis. N. W. Lord. (Power, Apr. 13, 1909; 3 pp.) A discussion of the chief things coal users wish to know, with notes on the value of the various methods used in analyzing coal. Paper before the Illinois Fuel Conference at Urbana, March 13, 1909.

9381—**BITUMINOUS COAL**. Methods of Firing Cheap Grades of Bituminous Coal. William Kavanaugh. (Elec. Wld., May 6, 1909; 1 p.) A discussion of six different methods for firing with soft coal, with notes on the advantages of each. Illustrated. 20c.

9382—**BRIQUET MAKING**. W. Galloway. (Proc. South Wales Inst. Engrs., Vol. XXVI, 1909; 47 pp.) Statistics and a general description of the process of briquetting, together with notes on the cost of installation and operation. A short description of a briquet plant at the Holland colliery, Westphalia. Illustrated.

9383—**COAL CUTTING MACHINES**. A Comparison of Coal-cutting Machines. Sydney F. Walker. (Eng. and Min. Journ., May 22, 1909; 4½ pp.) Notes in which various coal cutting machines are compared; a statement of costs which show the economy of machine mining; a discussion of compressed air as compared with electric power. 20c.

9384—**COAL DUST** to Date, and its Treatment with Calcium Chloride. Henry Hall. (Trans. Min. Inst. of Scotland, Vol. XXXI, Part 4, 1909; 38 pp.) A short review of coal dust literature; tests of coal dust in airways; effects of watering; effects of calcium chloride treatment of dust and a description of the dust problem.

9385—**COAL DUST PROBLEM**. The John Verrier. (Mines and Minerals, May, 1909; 3 pp.) Discusses the mechanical influence of air currents in furnishing conditions favorable to dust. Illustrated. 20c.

9386—**COKE**—Donkey Coke Company. C. R. King. (Mines and Minerals, May, 1909; 4 pp.) A description of the plan of the works and mine, arrangements for economic expansion and contraction of output; and notes on the manning of the liquor question. Illustrated. 20c.

9387—**COKE**—Koppers By-Product Coke Oven Plant at Joliet. R. Gunderson. (Progressive Age, May 1, 1909; 2½ pp.) A general description of a plant of 280 by-product coke ovens now in use at the works of the Illinois Steel Company. Illustrated. 20c.

9388—**COKE**—The Genesis and Development of the Coking Oven. W. Galloway. (Proc. South Wales Inst. Engrs., Vol. XXVI, 1909; 12 pp.) An historical review of the coke industry covering a period of over 200 years. Illustrated.

9389—**COLORADO**. The Grand Mesa Coal Field, Colorado. Willis T. Lee. (Bull. No. 341-C, U. S. Geol. Surv., 1909; 20 pp.) General notes on the geology and geography of the district, together with short descriptions of some of the coal deposits. Illustrated.

9390—**COLORADO AND NEW MEXICO**. The Coal Field Between Durango, Colorado, and Monero, New Mexico. James H. Gardner. (Bull. No. 341-C, U. S. Geol. Surv., 1909; 13 pp.) A short description of the geology of the district, together with some notes on the various coal beds. Illustrated.

9391—**COLORADO AND UTAH**—Coal Fields of Northwestern Colorado and Northwestern Utah. H. S. Galloway. (Bull. 341-C, U. S. Geol. Surv., 1909; 55 pp.) A preliminary statement of the results of investigations in these fields during 1907, dealing with their geology and giving the initial description of the coal fields, illustrated by geologic maps.

9392—**COST OF MINING**. An Investigation of the Cost of Mining Coal. J. H. Finlay. (Eng. and Min. Journ., May 8, 1909; 2½ pp.) An analysis of the operating cost of the coal fields, illustrated by geologic maps. In which it is shown that the rate of wages is an effect and not a cause in the economy of mining. 20c.

9393—**ELECTRICAL PLANTS**. Notes on Safety of Work in Electrical Plants in Coal Mines. S. A. Simon. (Electrician, Apr. 9, 1909; 2 pp.) A consideration of the precautions necessary in installing and employing electrical apparatus in the mines, with notes on tests carried out some years ago in Europe to determine the value of enclosing electrical conductors as a protection against explosion. Illustrated. 1c.

9394—**EXPLOSION**—Notes on the Norton Hill Colliery Explosion. H. M. Morgans. (Eng. and Min. Journ., May 15, 1909; 1½ pp.) A discussion of the action of fire damp and coal dust in mine explosions, with comments on the mine inspector's report of the disaster. 20c.

9395—**EXPLOSIONS**. Mine Explosions as Related to Earthquakes. W. A. Spalding. (Eng. and Min. Journ., May 1, 1909; ½ p.) A supplemental list of coincidences and close approximations of earthquakes and mine explosions. 20c.

9396—**EXPLOSIVES**. Relation of the Use of Powder to Mine Accidents. Blaise Piedmont. (May 15, 1909; 1½ pp.) Statistics on the use of powder in mines showing that an excess of powder invariably results in greater fatalities. Illustrated. 20c.

9397—**GEOLOGY**. Petroleum and Coals. Eugene Coste. (Can. Min. Journ., May 15, 1909; 5 pp.) A discussion of petroleum and coal; a comparison of their nature, mode of occurrence and origin. To be continued. 20c.

9398—**GREAT BRITAIN**. The Wemyss Coal Field. John Gemmell. (Trans. Min. Inst. Scot., Vol. XXXI, Part 4, 1908; 19 pp.) An historical review of the coalfield, and modern development, along the line of exploitation, shaft sinking and pumping machinery.

9399—**HOISTING**. A Welsh Electric Hoisting Plant. A. H. Bridge. (Elec. Rev., May 1, 1909; 2 pp.) A description of an electric hoisting plant operating in a north-west at the Marlinth Pit of the Great Western Colliery Company, capacity 175 tons per hour from a depth of 1100 ft. Illustrated. 20c.

9400—HOISTING—Three Thousand Horse Power Winding Engine. J. B. Van Brussel. (Eng. and Min. Journ., May 1, 1909; 1½ pp.) The description of a winding engine plant recently installed in an English colliery near Brussels. Illustrated. 20c.

9401—ILLINOIS—The Carterville Coal Field, Southern Illinois. R. S. Moss. (Min. Wild., Apr. 10, 1909; 2 pp.) An historical review of coal mining in Southern Illinois, together with a description of a number of the principal mines, including the washer and tipple of the Madison Coal Corporation. Illustrated. 20c.

9402—INDIA—Longwall Working at the Seeterampore Coal Company's Collieries, Narsamooda, India. Willis Howarth. (Iron and Coal Tr. Rev., Apr. 30, 1909; 1 p.) A discussion of the longwall method of mining in India, with special reference to the physical conditions of the locality, the human conditions and the mechanical conditions which confront the engineer in charge. Illustrated. 40c.

9403—MONTANA—The Coal-mining Industry of Montana. J. P. Rowe. (Eng. and Min. Journ., Apr. 24, 1909; 5½ pp.) A review of each county in the district, together with a scale of day wages and schedule of mining rates. Illustrated. 20c.

9404—NEW MEXICO—The Coal Field Between Gallup and San Mateo, New Mexico. James L. Gardner. (Bull. No. 341-C, U. S. Geol. Surv., 1909; 16 pp.) Notes on the topography, geology and coal deposits at Gallup, New Mexico. Illustrated.

9405—OREGON—The Rogue River Valley Coal Field, Oregon. J. S. Miller. (Bull. No. 341-C, U. S. Geol. Surv., 1909; 5 pp.) Notes on the geology and coal deposits of Southern Oregon. Illustrated.

9406—PEAT—A New Gas Producer for Peat. Otto K. Zwingerberger. (Journ. Am. Peat Soc., Apr., 1909; 5 pp.) The author discusses the advantages and disadvantages of peat as a fuel and gives a description of a new producer for peat. Illustrated. 60c.

9407—PEAT—Fuel from Peat. M. Eckenberg. (Iron and Steel Institute, May, 1909; 32 pp.) Researches and experiments with the object of finding a suitable producer for peat, and giving a description of the process. Illustrated.

9408—PEAT—Indiana Peat, Its Origin and Value. A. E. Taylor. (Journ. Am. Peat Soc., Jan., 1909; 4 pp.) The author describes the various peat deposits of the State giving their area and their geological features. To be continued. 60c.

9409—PEAT—The Utilization of Peat. Samuel L. Jodid. (Journ. Am. Peat Soc., April, 1909; 12 pp.) The author gives a description of the peat deposits of Michigan and chemical analyses of various samples, together with notes on their calorific value. 60c.

9410—PEAT DEPOSITS of Maine. Edson S. Bastin and Charles A. Davis. (Bull. No. 376, U. S. Geol. Surv., 1909; 127 pp.) A discussion of the origin and formation of peat, the various deposits in Maine, its uses and detailed descriptions of the principal localities in which it occurs.

9411—PHILIPPINE ISLANDS—The Coal Resources of the Philippine Islands. Warren D. Smith. (Econ. Geol., April, 1909; 15 pp.) An historical review of coal mining, and notes on the geology of the islands. The author gives a detailed description of a number of the principal fields, together with tables of analyses and commercial tests of the coal. Illustrated. 60c.

9412—PULVERIZED COAL—The Use of Pulverized Coal for Foundry Purposes. Richard K. Meade. (Am. Foundrymen's Assn., 1909; 6 pp.) Notes on pulverized coal, chemical analyses, and methods of turning powdered coal.

9413—PURCHASE OF COAL—Results of Purchasing Coal Under Government Specifications. John Shober Burrows. (Bull. No. 378, U. S. Geol. Surv., 1909; 44 pp.) Some notes on the value of coal as a fuel and the general character of the Government contracts for the year 1909. Also a paper on Burning the Small Sizes of Anthracite for Heat and Power Purposes, by Dwight T. Randall.

9414—QUEENSLAND—Cooktown Coalfield. L. C. Ball. (Queensland Govt. Min. Journ., Apr. 15, 1909; 5 pp.) A general description of the topography and geology of the district. Also notes on the principal coal crops. Illustrated. 60c.

9415—RESCUE APPARATUS—Practical use of Apparatus of Colliery Rescue Apparatus, and the Organization of Rescue Corps. George Blake Walker. (Trans. Am. Inst. Min. Eng., Vol. XXXI, Part 1, 1909; 19 pp.) A general discussion of rescue apparatus, the organization of parties and leaders, and notes on what to do in case of accident.

9416—RESERVOIR SITES—Safety of Ground Beneath Reservoirs. Arthur Lakes. (Min. Sci., Apr. 29, 1909; 1¼ pp.) A de-

cussion of the geological aspects of reservoir sites, the problems which at times arise and the part which a knowledge of geology would solve. Illustrated. 20c.

9417—SURVEYING—Modern Practice in Surveying. T. A. O'Donohue. (Min. Eng., May, 1909; 2 pp.) The continuation of a series of articles on surveying, in which the author compares various methods and gives some notes on chain surveying. Illustrated; 20c.

9418—UNITED STATES—The Coal Fields of the United States. M. R. Campbell and E. W. Parker. (Trans. A. M. E., April, 1909; 2 pp.) The geographical distribution of the coalfields and statistics on the output of each field. Also notes on the duration of supply, the annual production and waste in coal mining. 20c.

9419—UTAH—The Harmony, Colob, and Kanab Coal Fields, Southern Utah. G. B. Richardson. (Bull. No. 341-C, U. S. Geol. Surv., 1909; 23 pp.) Notes on the geography, geology and coal deposits in Southern Utah, together with chemical analyses. Illustrated.

9420—VENTILATION—An Inquiry into the Ventilation of Coal Mines and the Methods of Examining for Fire-damp. (Iron and Coal Tr. Rev., May, 1909; 1½ pp.) Notes on a standard for mine ventilation as considered by the British Royal Commission on Safety in Mines. Observations on the flames of fire-damp in the atmosphere containing fire-damp. Illustrated. 40c.

9421—VIRGINIA—The Pocket Coal District, Virginia, in the Little Black Mountain Coal Field. Assisus A. Fisher. (Bull. No. 341-C, U. S. Geol. Surv., 1909; 10 pp.) Notes on the geologic occurrence of coal in Western Virginia, together with a detailed description of the various coal fields, their character of the coal, its chemical properties and coking qualities. Illustrated.

9422—WASHERY—A New Coal Washery in Michigan. Lee Fraser. (Eng. and Min. Journ., May 15, 1909; 1¼ pp.) A description of a new coal washer built by the Link Belt Company of Chicago, for the Consolidated Coal Company at Saginaw, Michigan. Illustrated. 20c.

9423—WEST VIRGINIA—Raleigh County Mining Methods. H. H. Stock. (Altnes and Minerals, May, 1909; 5 pp.) A description of the developments being carried on in Raleigh county, West Virginia, together with notes on the methods now in use and the proposed changes. Illustrated. 20c.

COPPER

9424—ALASKA—Railroads of the Copper River District, Alaska. H. S. Taylor. (Min. Wild., May 15, 1909; 10 pp.) Notes on the railroads operating in various parts of Alaska, together with an outline of the resources of the country that will be developed by them. Illustrated. 20c.

9425—ALASKA—The Big Bonanza Copper Mine, Latouche Island, Alaska. Francis C. Lincoln. (Econ. Geol., April, 1909; 13 pp.) Notes on the geography, history and mining of the mine. Also a general economic geology and the mineral deposits. Illustrated. 60c.

9426—ANALYTICAL METHOD—Notes on the Iodide Method for Copper. R. T. D. Williams. (Aust. Min. and Eng. Rev., Apr. 5, 1909; 1 p.) Some notes on the use of iodide method as employed in the Wallaroo district. Comparisons are made with the electrolytic method. 40c.

9427—BRASS—The Manufacture of Red Brass Ingot; Its Uses and Advantages. W. M. Corse. (Am. Brass Founders' Assn., 1909; 7 pp.) This paper gives an account of the manufacture of high grade red brass in order that foundrymen may understand something about it and why it is now extensively used.

9428—BRASS MELTING—Notes on Brass Melting. Charles T. Bragg. (Am. Brass Founders' Assn., 1909; 8 pp.) A discussion of the important factors necessary to the successful smelting of alloys.

9429—ELECTRICAL EQUIPMENT at Wallace and Mounta. (Aust. Min. Stand., Apr. 7, 1909; 1½ pp.) A brief description of the electrical equipment of the Wallaroo mine, smelting works and electrolytic refineries. Illustrated. 40c.

9430—GERMANY—German Electrically Operated Copper Mines. Frank C. Perkins. (Min. Wild., Apr. 10, 1909; 1½ pp.) A description of the electrical equipment of the copper mines in Germany. Illustrated. 20c.

9431—MICROSTRUCTURE OF COPPER—An Essay with a New Etching Reagent. Robert R. Abbott. (Eng. and Min. Journ., Apr. 10, 1909; 1¼ pp.) A description of the method of etching copper by the use of a new etchant. Illustrated. 20c.

9432—MILL—The Mill of the Ohio Copper Company. (J. Min. Sci., Apr. 1909; 2½ pp.) A de-

scription of the structure, equipment and operation of a 2250-ton mill. Illustrated. 20c.

9433—MINE WATER—Precipitation of Copper from Batte Mine Water. Charles J. Stone. (Eng. and Min. Journ., May, 1909; 2 pp.) A description of the methods employed for the recovery of copper from mine water and notes on the leaching of old tailings dumps. Illustrated. 20c.

9434—NEVADA—The Nevada-Douglas Copper Properties, Nev. W. S. Zehring. (Min. Wild., April 17, 1909; 2½ pp.) A description of the geology and ore deposits of the Douglas group, with some notes on the operations of the Nevada-Douglas mine. Illustrated. 20c.

9435—NEVADA—The Yerington Copper District, Nevada. Frederick L. Ramsome. (Bull. No. 380-B, U. S. Geol. Surv., 1909; 26 pp.) The author gives some notes on the geology of the district, the ore deposits, together with a description of some of the principal mines. Also a list of the survey publications on copper.

9436—PRODUCTION—Copper Production in 1908 and the Present Outlook. John B. Kershaw. (Econ. Rev., May 1, 1909; 1½ pp.) Statistics on the production of copper from 1900 to 1908, price variations and the present outlook. Illustrated. 20c.

9437—SMELTER—The Saco Smelter and Power Plant, Saco, Ariz. S. S. Shafter. (Min. Wild., Apr. 17, 1909; 1 p.) A description of the smelter, its location and operation. Illustrated. 20c.

9438—SMELTING—Flint Copper Smelting Process. (Northwestern Min. Journ., March, 1909; 2 pp.) A description of the trial run of the Flint smelter, the experimental plant and a comparison of costs with other methods. Illustrated. 20c.

9439—SMELTING COSTS—Costs of Lake Superior Smelting. J. S. Austin. (Min. and Sci. Press, Apr. 24, 1909; 1½ pp.) Interesting data on the cost of smelting at these works, which are compared with the Isle Royale, Osceola, Tamarack and Ahmeek mines. 20c.

9440—SMELTER METHODS of Greene-Canaan Copper Company. (Min. Wild., May 8, 1909; 1½ pp.) Notes on the methods of mining the ores from the various mines and the methods of transportation. Illustrated. 20c.

9441—UTAH—Boston Consolidated, Bingham, Utah. C. DeKalb. (Min. and Sci. Press, Apr. 17, 1909; 3½ pp.) A description of the orebodies and the methods of handling the ores. Also some notes on the system of cave mining. Illustrated. 20c.

9442—UTAH COPPER MINE, The Courtney de Kalb. (Min. and Sci. Press, Apr. 10, 1909; 5½ pp.) A description of the mine and the mining methods with a special note on the application of steam shovel to the mining of low-grade copper ores. The caving system is also described. Illustrated. 20c.

FLUORSPAR

9443—KENTUCKY FLUORSPAR and Its Value in the Iron and Steel Industries. E. E. Fols. (Trans. A. M. E., April, 1909; 13 pp.) A description of the Memphis mine as a typical example of fluorspar mining. Notes on the origin of the deposits, fluorspar mills and the use of fluorspar in the metallurgy of iron and steel.

GOLD AND SILVER

9444—AMALGAMATION—Electrochemical Amalgamation in Lixivation. Elmer E. Carey. (Min. Wild., Apr. 17, 1909; 1½ pp.) The author calls attention to the improvements that can be made by employing the electrochemical method in connection with lixiviation and amalgamation. His results are based on a series of experiments. 20c.

9445—ASSAYING—A Cheap Platinum Parting Apparatus. G. H. Stanley. (Journ. Chem. Met. and Min. Sci., South Africa, Feb., 1909; 2 pp.) The title is misleading. This is a description of an apparatus made of platinum to be used in parting of gold and silver assays. Illustrated. 60c.

9446—COBAT—The Nipissing Mine, Cobalt, Ontario, as It Is Today. Alex. Gray. (Min. Wild., Apr. 24, 1909; 1½ pp.) The author gives a description of the Nipissing mine, the organization of the company, its ore deposits, the amount of silver produced and an estimation of the ore reserves. 20c.

9447—CYANIDATION at Mercer, Utah. L. A. Palmer. (Min. Wild., Apr. 10, 1909; 3½ pp.) A description of the Consolidated Mercer mill, its equipment and methods of operation. Also some notes on milling costs. Illustrated. 60c.

9448—CYANIDATION OF SILVER ORES—Cyanidation of Parral Silver Ores, El T. Willis. (Min. and Sci. Press, Apr. 3,

1909; and Mex. Min. Journ., May, 1909; 2 pp.) A short historical review of the cyanide process in Mexico, the names of a number of the principal mining companies using this process, together with their daily capacity and some notes on the modern practice. 20c.

9449—CYANIDATION OF SILVER ORES.—H. Mosher. (Min. and Sci. Press, March 15, 1909; 3 p.) The object of this paper is to direct the attention of cyanide operators to possibilities still lying dormant, which will give a greater range in the treatment of low-grade silver ore. 20c.

9450—CYANIDATION OF SILVER ORES.—T. P. Holt. (Min. and Sci. Press, Apr. 17, 1909; 2 pp.) The tabulation of laboratory results of a series of experiments on silver ores and minerals. 20c.

9451—DREDGING at Butte. A. Floyd Bushnell. (Eng. and Min. Journ., May 15, 1909; 1½ pp.) A description of the operations of the British Revere Mining Company's dredge which is operating at Rocker, Montana. Illustrated. 20c.

9452—DREDGING—Development of Dredges for Placer Deposits. George B. Massey. (Eng. and Min. Journ., Apr. 22, 1909; 2½ pp.) A discussion of the development of dredges and description of the operations on Bonanza Creek, Yukon Territory. Also notes on dredging costs. Illustrated. 20c.

9453—DREDGING—Examination of Gold Dredging Properties. T. S. Ruh. (Eng. and Min. Journ., May 1, 1909; 1½ pp.) Notes on methods used for sampling placer grounds. Illustrated. 20c.

9454—DREDGING—Hydraulic Dredging for Gold-Bearing Gravels. H. G. Granger. (Trans. A. I. M. E., April, 1909; 21 pp.) History of suction dredging in gold-bearing gravel and applications for a hydraulic gold dredge. Also notes on capacity and costs. Illustrated. 20c.

9455—DREDGING—Restoring Dredged Ground. (Eng. and Min. Journ., May 8, 1909; 2 pp.) Description of a method for restoring the dredged area to usefulness as employed in Victoria, Australia. Notes on the advantages of the system. Illustrated. 20c.

9456—DREDGING CONDITIONS in Colombia. A. P. Rogers. (Eng. and Min. Journ., May 15, 1909; ¾ p.) Note on the climatic and economic conditions governing dredging operations. 20c.

9457—DREDGING INDUSTRY in New Zealand. A. C. Buckland. (Min. Journ., May 1, 1909; 1 p.) A brief historical review of dredging in New Zealand, together with some notes on the present status of the industry. 40c.

9458—ECONOMICAL MINING The "Wholesale" Idea in Gold Mining. W. R. Feldmann. (Bull. No. 75, A. I. M. E., 13 pp.) The author attempts to make plain some aspects of a policy of increasing reduction plant up to the practicable producing limit of a mine as to increase production between larger scale working and the best economic results. Illustrated. 20c.

9459—FINE GRINDING—Tube Mills, Wet and Dry. Max Trotter. (Aust. Min. and Eng. Rev., Apr. 3, 1909; 7 pp.) A short history of tube mill grinding, the advent of the grinding pan; modern tube mill lining; the advantages of tube mills for fine grinding and re-entrainment of tailings. Illustrated. 40c.

9460—FINE GRINDING TESTS: Tube Mill and Grinding Pans. Broken Hill South Mine. W. E. Walnwright and W. J. McBride. (Proc. Aust. Inst. Min. Eng., Feb., 1909; 23 pp.) A series of tests in which grinding pans and tube mills are compared to determine which is the more efficient as well as economical. The results given are in favor of the tube mill. Illustrated. 20c.

9461—GERMAN Silver-Lead Mining in Froberg, Germany. Wilton G. Brown. (Eng. and Min. Journ., May 15, 1909; 2 pp.) A brief history of the mining industry from 1820 to the present time, together with a review of the operations in 1908 and notes on concentration, smelting and refining. 20c.

9462—HYDRAULIC SLUICING on the Tejuil River, Victoria. A. N. Macneil. (Aust. Min. and Eng. Rev., Mar. 5, 1909; 2½ pp.) An historical review of hydraulic sluicing together with some notes on the deposits and a description of the works of two of the largest companies. Illustrated. 20c.

9463—IDAHO—Vein Structure in the Monument Mine. Henry C. Carr. (Min. and Sci. Press, Apr. 17, 1909; 1½ pp.) Some notes on the geological structure of the ore deposits and a short description of the mine itself. Illustrated. 20c.

9464—MEXICO—Chalchihuites Gold Mine. Charles W. Geddes. (Min. and Sci. Press, May 15, 1909; 1½ pp.) A description of the Chalchihuites mine which is near the

junction of the States of Chihuahua, Sinaloa, and Durango, Mexico. Illustrated. 20c.

9465—MILLING in the Cripple Creek District, Colorado. S. A. Worcester. (Eng. and Min. Journ., May 8, 1909; 1½ pp.) Notes on mills that were failures; a list of expenses; the design of milling plants; and mining and milling costs. 20c.

9466—MINING METHODS in the North—IV. T. A. Rickard. (Min. and Sci. Press, Apr. 24, 1909; 5 pp.) Notes on mining methods in Alaska, equipment and mining costs. Illustrated. 20c.

9467—MOUNT MORGAN ORES—Metallurgical Treatment of Mount Morgan Ores. J. Bowle Wilson. (Eng. and Min. Journ., Apr. 24, 1909; 2 pp.) A description of the chlorination process and its development to suit the peculiarities of the ore. Also notes on copper smelting. Illustrated. 20c.

9468—NEVADA—The Johnnie Mining and Milling Company. Will C. Hilgins. (Salt Lake Min. Rev., Apr. 15, 1909; 3½ pp.) A description of the geology, development, mine development and equipment and some notes on the mill, its equipment and operation. Illustrated. 20c.

9469—NOVA SCOTIA—A Practical Suggestion for Testing the Gold Mines of Nova Scotia. Fred P. Rannan. (Journ. Min. Soc. Nova Scotia, Vol. XII, Part I, 1909; 6 pp.) Notes on the willingness of the government to furnish financial assistance in order to develop mineral properties.

9470—ONTARIO—Consolidation of the La Rose-Lawson Properties. Alex. Gray. (Min. Wld., May 8, 1909; 1½ pp.) A short description of each of these two properties with a description of the present organization. Illustrated. 20c.

9471—ONTARIO—Impressions of a New Ontario Camp—Gowganda. H. E. West. (Eng. and Min. Journ., May 1, 1909; 2½ pp.) Description of the topography and vein systems of the Gowganda district, together with notes on the transportation problem from the economic standpoint. 20c.

9472—ORE PREPARATION—New Type of Washers—Lowercase Gold Ore. Joseph Hyde Pratt. (Eng. and Min. Journ., May 8, 1909; 3½ pp.) The description of a machine which has been found superior to other types described for use in the South Atlantic States, as employed at the Shuford mine. Illustrated. 20c.

9473—PLACER MINING INDUSTRY on the Pacific Coast. Dennis H. Stovall. (Min. Wld., Apr. 17, 1909; 1 p.) A short historical review of placer mining with special reference to Northern California and Southern Oregon. Illustrated. 20c.

9474—PRECIPITATION—Notes on Precipitation. M. Smith. (Journ. Chem. Met. and Min. Soc. of South Africa, March, 1909; 24 pp.) Some notes on the amount of zinc shavings necessary to precipitate one ton of solution in 24 hours; the effects of an excess of zinc and the construction of precipitation boxes. 60c.

9475—QUEENSLAND—The Etheridge Goldfield. Queensland. W. W. Pegibon. (Min. Wld., Mar. 1, 1909; 1½ pp.) Notes on the location, topography, economic conditions and the orebodies of this field. Illustrated. 40c.

9476—RAND GOLD PRODUCTION—The Distribution of the Gold Produced on the Rand. T. Kirke Rose. (Journ. Chem. Met. and Min. Soc. of South Africa, Feb., 1909; 3 pp.) This is a compilation of statistics from the various Government publications showing imports of gold into the United Kingdom together with exports of gold bullion from the Rand. 60c.

9477—RAXIS MINES—The Valuation of Mining Areas on the Rand. W. F. Wilkinson. (I. M. M. Bull. No. 55, Apr. 15, 1909; 7 pp.) A discussion of mine valuation, together with notes on capital expenditure, profitable tonnage, working costs and rate of interest required.

9478—SIBERIA—Gold and Other Minerals of Eastern Siberia. S. F. G. White. (Eng. and Min. Journ., May 22, 1909; 1½ pp.) A description of the gold quartz veins in the Province of Bakal. Also notes on the placer deposits which are worked by primitive methods. 20c.

9479—SLIME TREATMENT—Further Notes on the Utilization of Waste Heat in Slimes Treatment. A. Salkinson. (Journ. Chem. Met. and Min. Soc. of South Africa, March, 1909; 1½ pp.) Notes on the utilization of waste heat from boilers as employed by the Simmer & Jack East, Ltd. mines. 60c.

9480—SLIME TREATMENT—Improvements in the Treatment of Slimes by the Filtrate Process. Arthur W. Allen. (Eng. and Min. Journ., May 15, 1909; 1 p.) Notes on the simultaneous displacement of pulp with wash solutions as employed at the Palmarejo & Mexican Goldfields Com-

pany's plant at Zapote, Mexico. Illustrated. 20c.

9481—SOUTH AFRICA—The Pilgrim's Rest Gold Fields and Mining Methods. J. Mayle Phillips. (Journ. Chem. Met. and Min. Soc. of South Africa, March, 1909; 19 pp.) Notes on the geography, history, geology and a description of the mining methods employed. Illustrated. 60c.

9482—STAMP MILL—The 100-Stamp Dorr Mill at Millers, Nevada. A. H. Martin. (Min. Wld., Apr. 24, 1909; 2½ pp.) A description of the mill and its equipment, together with some notes on the cyanide process. Illustrated. 20c.

9483—STAMP MILLS—The Economics of Stamp Mills. G. A. Robertson. (So. African Min. Journ., Mar. 27, 1909; 1 p.) A discussion of stamp milling and the advocating of larger shoes and dies. Notes on the heavy stamp head policy. 20c.

9484—VICTORIA—Mining in Victoria—The St. Annand Field. E. J. Dunn. (Aust. Min. Stand., Mar. 31 and Apr. 7, 1909; 14 pp.) Notes on the geology of the district, the ore deposits and mining operations of a number of the principal mines in Victoria. 60c.

9485—VICTORIA—Southern End of the Rendigo Goldfield. Donald Clark. (Aust. Min. Stand., Apr. 7, 1909; 15 pp.) Some notes on the geology of the district, together with a short description of the Goldfields South mine, and the Victoria Proprietary New Chum Mine. Illustrated. 40c.

9486—WASHINGTON—Development in the Orient District. Washington. B. N. Sharpe. (Min. Wld., May 8, 1909; 1½ pp.) Notes on the early history, location and geography of the district. A number of the important prospects and mines are mentioned. Illustrated. 20c.

IRON AND STEEL

9487—AGEING OF MILD STEEL. The Influence of Nitrogen. C. E. Stromeier. (Iron and Steel Institute, May, 1909; 19 pp.) A series of experiments with tabulated results showing the effect of phosphorus and nitrogen on the tensile and bending strength of various steels. 40c.

9488—ALLOY STEELS for Motor-Car Construction. John A. Mathews. (Journ. Frank. Inst., May, 1909; 19 pp.) The author discusses certain economic phases of the subject, together with some matters of shop expediency and the relation of various manufacturing methods to the quality of the finished parts. 60c.

9489—BRISTOL FURNACE LININGS—Firebrick for Blast Furnaces. Iron Age, Apr. 29, 1909; 1½ pp.) Notes on the defects which shorten the life of furnace linings with suggested remedies. 20c.

9490—BLOWING ENGINES—The Two-Cycle Gas-Blowing Plant at the Works of the Frodingham Iron and Steel Company, Ltd. (Iron and Coal Tr. Rev., May 7, 1909; 10 pp.) A description of the plant containing four single cylinder compressors, each installed by the Frodingham Iron and Steel Company. Illustrated. 40c.

9491—CALIFORNIA—Iron Mining and Smelting in California. Al H. Martin. (Min. Sci., Apr. 15, 1909; 1½ pp.) An account of the extent, development and character of the iron-ore deposits of Shasta county, California, and of the methods of reduction. Illustrated. 20c.

9492—CARBON AND PHOSPHORUS—Note on the Determination of Carbon and Phosphorus in Steel. Andrew A. Blair. (Iron and Steel Institute, May, 1909; 10 pp.) A description of the various methods used for determining phosphorus and carbon in steel. 20c.

9493—CASTINGS—Notes on Air Furnace Construction for Malleable Castings. W. H. Kinn. (Aust. Foundrymen's Assn., 1909; 7 pp.) A description of a type of furnace used for high castings and chilled iron work. Illustrated. 20c.

9494—CASTINGS—Open-Hearth Methods for Steel Castings. W. H. Kinn. (Aust. Foundrymen's Assn., 1909; 7 pp.) A description of a small open hearth furnace with notes on its advantages in producing steel castings. Illustrated. 20c.

9495—CORROSION—The Electrolytic Theory of the Corrosion of Iron and Its Applications. William H. Walker. (Iron and Steel Institute, May, 1909; 47 pp.) The author discusses the fundamental concepts involved in modern electrolytic theory of the corrosion of iron, and points out some practical applications of his theories to the corrosion of iron as met in engineering practice. Illustrated. 20c.

9496—CORROSION—The Preservation of Iron and Steel. Albert S. Cushman. (Iron and Steel Institute, May, 1909; 42 pp.) Notes on the corrosion of iron and steel, the effects of zinc, tin, lead and other metals; with

remarks on preservation with paint coatings, varnishes, bitumens and enamels. Illustrated.

9497—CORROSION—The Value of Physical Tests in the Selection and Testing of Protective Coatings for Iron and Steel. J. Cruickshank Smith. (Iron and Steel Institute, May, 1909; 10 pp.) The author indicates the trend of technical opinion in regard to the principles to be followed in the testing and technical valuation of various paint materials.

9498—DECARBILIZATION OF IRON CARBON ALLOYS—The Chemical Physics Involved in the Decarbilation of Iron-Carbon Alloys. W. H. Hatfield. (Iron and Steel Institute, May, 1909; 16 pp.) A series of microscopic and chemical experiments to determine the chemical physics of the decarbilation of white iron. Illustrated.

9499—DRY AIR BLAST—Economies in the Manufacture of Iron and Steel at the Waterhouse. (Eng. Mag., May, 1909; 12 pp.) An historical review and discussion of the Waterhouse process, with notes on results obtained and theoretical considerations. Illustrated. 40c.

9500—DRY AIR BLAST—Refrigerating Plant in Steel Works. Osborn Monnett. (Pow. & Appl., 1909; 3½ pp.) A description of the largest plant to exist for dry air or dry air supply to blowing engines. Illustrated. 20c.

9501—ELECTRIC FURNACE—Small Experimental Heroult Furnace. C. A. Hansen. (Electrochem. and Met. Ind., May, 1909; 2½ pp.) A detailed description of an experimental furnace, its electrodes, power consumption, metal losses, lining and quality of output. Illustrated. 40c.

9502—ELECTRIC HARDENING FURNACES. (Engineering, Apr. 16, 1909; 1½ pp.) The author gives a description of three furnaces, together with notes on their operations. Illustrated. 40c.

9503—ELECTRIC SMELTING—The Electric Furnace and Electrical Process of Steel Making. W. Rodenbaur. (Iron and Steel Institute, May, 1909; 34 pp.) A comparison of the merits of the methods of making steel electrically and of the furnaces in which this is done. Special reference and description is given concerning the Röchling-Rodenbaur furnace. Illustrated.

9504—FERRO-MANGANESE—Further Experiments on the Preparation of Carbon-Free Ferro-Manganese. E. A. Wright. (Iron and Steel Institute, May, 1909; 16 pp.) This paper briefly embodies a series of experiments carried out in the laboratories of the Royal School of Mines, with the object of obtaining a carbon-free metal.

9505—FOUNDRIES—Some Considerations on the Use of Electricity in Foundries. J. W. Warr. (Elec. Rev., Lond., Apr. 16, 1909; 2½ pp.) Some notes on the application of electricity in the foundry, especially connected with engineering factories, but work for the trade generally and for odd customers. 40c.

9506—FOUNDRY BUILDING—A Concrete Foundry Building in Germany. H. Pray Kieffer. (Cement Age, April, 1909; 6 pp.) A description of concrete foundry building of the Siemens & Halske Actiengesellschaft in Solingen. To be concluded. 20c.

9507—HARDNESS OF STEEL—Notes on Tests for Hardness. Thomas Turner. (Iron and Steel Institute, May, 1909; 14 pp.) A brief comparison of four typical methods of measuring hardness. The methods described are Turner's Sclerometer, Shaw's Scleroscope, Brinell's Test and Knoop's Test.

9508—HEAT TREATMENT STUDY of Bessemer Steels. Andrew McWilliam and E. J. Barnes. (Iron and Steel Institute, May, 1909; 27 pp.) A series of laboratory tests with tabulated results of heat treatment on ordinary commercial English acid bessemer steels, containing 0.1 to 0.86 per cent. carbon. Illustrated.

9509—HIGH-SPEED STEEL—A Suggested Theory. H. C. H. Carpenter. (Iron and Coal Tr. Rev., May 7, 1909; 1 p.) Notes on the varieties of the structure of high-speed steels and interpretation of cooling curves. 40c.

9510—HIGH SPEED STEEL—Annealing High-Speed Steel. O. M. Becker. (Am. Machinist, Apr. 24, 1909; 1½ pp.) Notes on quick and slow annealing, annealing temperatures and the effect of overheating and underheating. 20c.

9511—HIGH SPEED STEEL—Temperature Determination and Control for High-Speed Steel Treatment. O. M. Becker. (Eng. Mag., May, 1909; 12 pp.) The author emphasizes the importance of accurate temperature determinations in the manufacture of high-speed steel tools, and discusses the principles and uses of pyrometers designed for direct exposure to the heat to be measured. Illustrated.

9512—HIGH SPEED STEEL—The Tempering of High Speed Steel. O. M. Becker

(Am. Machinist, Apr. 8, 1909; 2 pp.) A short description of barium chloride, sand, metal baths, oil baths and electrically used for tempering steel. 20c.

9513—HIGH SPEED STEELS—The Sewer British High-Speed Steels. (Am. Machinist, Apr. 8, 1909; 2 pp.) Gives diagrams which show the area of cuts and the cutting speeds recommended by Osborn & Co., Ltd., and also the results of trials made at the Sheffield testing works of Thomas Nash & Sons, Ltd. Illustrated. 20c.

9514 HIGH-TENSION STEELS. Percy Longmuir. (Iron and Steel Institute, May, 1909; 10 pp.) A series of experiments to determine the most serviceable type of steel for high tension and endurance purposes.

9515 MAKE SUPERIOR—The Great Iron Fields of the Lake Superior District. Robert B. Brinsmade. (Min. Sci., Apr. 22 and 29, 1909; 2 pp.) A continuation of article previously indexed, dealing with conditions on the Menominee Range; also a discussion of the drainage and pumping systems used, together with the casing and the shafts employed at the Pewabic mines. Illustrated. 40c.

9516—MAGNETIC SEPARATION of Ores and its Application to Spathe Iron (Siderite). W. L. B. Russell. (Iron and Coal Tr. Rev., May 7, 1909; 2½ pp.) Notes on the principles of separation; comparison of energy; iron ore separators; types of separators used and a description of the plant at Bruderslund. Illustrated. 40c.

9517—MOLDING SAND TESTS. (Am. Foundrymen's Assn., Bul. No. 1, 1909; 2 pp.) The author gives notes on the method of testing the fitness of molding sand together with tabulated results of a number of experiments.

9518—NICKEL STEEL—The Strength of Nickel-Steel Riveted Joints, with Special Reference to Resistance to Slip. Ernst Pross. (Iron and Steel Institute, May, 1909; 34 pp.) Brief account of experiments, with tabulated results, of four kinds of nickel-steel used for rivets. The tests were made on hand and machine riveted steel joints.

9519—ONTARIO—Report on the Examination of Some Ore Deposits in the District of Thunder Bay and Rainy River, Province of Ontario. F. Hille. (Ottawa, Canada, 1908; Department of Mines, Mines Branch, 65 pp.) A report on the iron mining lands of Western Ontario with special reference to the Matawin Range in which magnetite and hematite occur. Illustrated.

9520—ORANGE ISLAND BRIDGE at Dupresne Steel Works. (Eng. and Min. Jour., May 8, 1909; 1½ pp.) A description of 230-ft. span bridge with a cantilever extension of 65 ft. designed to handle 600 tons of ore per hour. Illustrated. 20c.

9521—PRODUCER GAS FIRED FURNACES in the Iron and Steel Industries—I. and II. Oskar Kugel. (Iron Tr. Rev., Apr. 8 and 15, 1909; 4 pp.) A description, together with illustrations, of a number of types of furnaces in common use in the iron and steel industries which are fired with producer gas. 40c.

9522 PRODUCTION AND CONSUMPTION—The World's Production and Consumption of Iron Ore. (Iron and Coal Tr. Rev., Apr. 16, 1909; 1½ pp.) A paper issued by the Board of Trade showing the production and consumption of iron ore and pig iron in the United Kingdom and principal foreign countries for a series of years ending with 1907. 40c.

9523—SOLUBILITY OF STEEL—Influence of the Treatment on the Solubility of Steel in Sulphuric Acid. E. Heyn and O. Bauer. (Iron and Steel Institute, May, 1909; 123 pp.) Notes on quenching at various temperatures, quenching in oil, heating; annealing; chemical composition and the nature of the acid employed as affecting the solubility of iron. Illustrated.

9524 SPINNING STEELS. In Theory and Practice. Walter Gieseler. (Iron and Steel Institute, May, 1909; 10 pp.) A summary of the results of investigations made upon steels alloyed with nickel, chromium and various elements to determine their resistance to alternating stresses.

9525—STEEL PLANT—The Works of the Indiana Steel Company—IV. and V. (Iron Tr. Rev., May 6 and 20, 1909; 1 p.) The second and fifth of a series of articles on the Indiana Steel Company, in which is given a description of the auxiliary shops and the character of the various products which leave the plant for the Gary plant. 40c.

9526 WROUGHT IRON AND STEEL—The Properties and Fatigue of Wrought Iron and Steel. Henry S. Friedrich. (Industrial Engineering, April, 1909; 1 p.) A series of experiments to determine the elasticity and strength of various kinds of wrought iron and steel under varying conditions. 40c.

LEAD

9527—ALAMOSITE, a New Lead Silicate from Mexico. C. Palache and H. E. Merwin. (Am. Jour. Sci., May, 1909; 3 pp.) A mineralogical description of a new lead silicate from Mexico, with its chemical composition. 60c.

9528—BROKEN HILL ORES—Treatment of Broken Hill Ores. W. Poole. (Queensland Govt. Min. Jour., February and March, 1909; 5½ pp.) Conclusion of article previously indexed. Notes on the softening, desilverizing and refining of base alloys; gold-silver alloys and lead refining. Illustrated. \$1.

9529—CONCENTRATING Difficult Lead Ores at Broken Hill. Gerard W. Williams. (Eng. and Min. Jour., May 8, 1909; 2 pp.) Description of the method of concentrating the ore at the Broken Hill Block 10 mine, including slime treatment, sampling and auxiliary concentration; also data of costs. 20c.

9530—CONCENTRATION of Silver-Lead Ores, Broken Hill. V. F. S. Low. (Aust. Min. Stand., Mar. 21, Apr. 7 and 14, 1909; 14 pp.) Some notes on the object to be obtained by ore concentration, and analysis of conditions confronting an engineer when handling an ore deposit, a description of the mill handling ore from Block 10 mine, Broken Hill, including transportation and crushing machinery, lifts, elevators and grinding mills. \$1.

9531—MISSOURI—History of Southeast Missouri Lead District. I. Otto Ruhl. (Min. Wld., Apr. 17, 1909; 3½ pp.) Some notes on the early history of lead mining at Flat River and Ilesboro, also, with a description of the topography, geology and ore deposits. Illustrated. 20c.

9532—NEW MEXICO—The Tres Hermanas Mining District. Waldemar Lindgren. (Bull. No. 386-C, U. S. Geol. Surv., 1909; 10 pp.) Some notes on the general geological features on the Tres Hermanas mining district, New Mexico, with a summary of the Survey publications on lead and zinc.

9533—SMELTING—Modern Silver Lead Smelting at Laurium, Greece. Henry F. Collins. (Eng. and Min. Jour., May 1, 1909; 2½ pp.) A description of the ores of the district, the structural features of the new blast furnace, and the handling of furnace products. Illustrated. 20c.

MANGANESE

9534—VIRGINIA—Manganese Deposits of Virginia. S. Mays Ball. (Eng. and Min. Jour., May 22, 1909; 3 p.) A short description of the manganese deposits along the James river and Shenandoah valleys. Analyses of a number of ores are given. 20c.

MICA

9535—MICA MINING. A. S. Atkinson. (Eng. and Min. Jour., May 8, 1909; 1½ pp.) Notes on mica mining in Canada; the mica of commerce; mining methods and a consideration of the physical properties. 20c.

NITRATE OF SODA

9536—CONSUMPTION—The Consumption of Nitrate of Soda in the United States. Charles E. Moore. (Jour. Ind. and Eng. Chem., May, 1909; 2 pp.) Statistics on the nitrate industry in the United States, in which the author shows the various industries and products in which the nitrate is used. 60c.

PETROLEUM

9537—BAKU PETROLEUM INDUSTRY During 1908. (Petrol. Rev., May 8, 1909; 2 pp.) Details statistics as given by the British Vice-Consul in his report. 40c.

9538—CALIFORNIA—Calorific Value of California Fuel Oil. R. E. Pease. (Petrol. Rev., May 13, 1909; 1 p.) Notes on the value of crude oil as compared with coal, with a table showing the calorific value of California fuel oils. 20c.

9539—EXTRACTING OIL FROM BORNEO BORDES—New Method of Extracting Oil from Borneo. Frodrik A. Talbot. (Eng. and Min. Jour., May 15, 1909; 2 pp.) The description of a system which employs a glassy cable equipped with absorbent material to extract oil from borholes. Notes on its installation at Borslaw. Illustrated. 20c.

9540 GEOLOGY—Petroleum and Coals. Eugene Coste. (Can. Min. Jour., May 15, 1909; 5 pp.) See under "Coal."

9541—OIL SHALE—The Working of Oil Shale at Pumpherson. William Caldwell. (Trans. Min. Inst. Scot., Vol. XXXI, Part 4, 1909; 8½ pp.) A short description of the shale formation, with notes on the methods of mining. Illustrated.

9542—ORIGIN OF PETROLEUM. The. L. Magoon. (U. S. Geol. Surv., May 8, 1909; 1 p.) A discussion of the geologic occurrences of petroleum and other hydrocarbons and their organic origin. To be continued. 40c.

9543—UTAH—The New Oilfield in Utah. A. J. Rogers. (Eng. and Min. Journ., May 15, 1909; 1 p.) A short description of the oilfield in southeastern Utah where four wells have been sunk. Illustrated. 20c.

PHOSPHATE ROCK

9544—ALGERIA AND TUNIS—Phosphate Deposits of Algeria and Tunis. (Am. Fertil. Rep., April, 1909; 1 1/2 pp.) A short description of the geology and of the phosphate deposits of Algeria and Tunis, together with chemical analyses. 20c.

PLATINUM

9545—RUSSIAN PLATINUM INDUSTRY and Its Regulation. E. de Bapstier. (Min. Journ., May 8, 1909; 1 1/2 pp.) Describes the occurrence of platinum placers in Russia, and gives statistics of production, consumption, prices, etc., also of the future prospects. 40c.

PRECIOUS STONES

9546—AMATRICE, A New Gem Stone of Utah. Edward R. Ziesler. (Eng. and Min. Journ., May 22, 1909; 2 pp.) Notes on the location, geology and occurrence of amatrice; also remarks on its origin, production and uses. Illustrated. 20c.

9547—BRAZIL—The Diamantina District of Minas Geraes. G. W. Lindsay. (Eng. and Min. Journ., Apr. 24, 1909; 2 1/2 pp.) Notes on the discovery and early production of diamonds, their occurrence and methods of diamond washing employed. 20c.

9548—BRAZIL—The Diamond-Bearing Highlands of Bahia. J. C. Branner. (Eng. and Min. Journ., May 15 and 22, 1909; 10 pp.) A very complete and comprehensive article, discussing transportation and climatic conditions, geology of the region, including source of the diamonds, mining methods and possibilities of increasing the diamond resources which are stated to be extensive, and gives notes on the mining laws of Brazil. Fully illustrated by map and photographs. 20c.

9549—DIAMONDS—Supposed Diamond-Bearing Volcanic Pipe. E. F. Pittman. (Aust. Min. Stand., Apr. 7, 1909; 1 p.) Notes on the diamond deposits of South Africa, together with a description of a supposed diamond-bearing formation at Snodgrass, N. S. W. 40c.

QUICKSILVER

9550—ANALYTICAL METHOD—A Volumetric Method for the Determination of Mercury. W. H. Craman. (Eng. and Min. Journ., May 22, 1909; 1 p.) A method based upon the formation of mercuric iodide when potassium iodide is added to feebly acid solutions of mercurous salt. 20c.

RARE METALS

9551—CERUIM—A Rapid and Accurate Volumetric Method for the Determination of Cerium in the Presence of other Rare Earths. P. J. Metzger. (Jour. Am. Chem. Soc., May, 1909; 3 pp.) A description of the method, solutions required and remarks on the process. 60c.

9552—PERU—The Occurrence of the Rare Metals in Peru. E. Weckwarth. (Min. Journ., Apr. 24, 1909; 2 1/2 pp.) Some notes on cerium, thorium, uranium, tungsten, thorium, vanadium and zirconium. 20c.

9553—TITANIUM—The Heat of Formation of Titanium Dioxide, and Third Paper on the Heat of Combination of Acidic Oxides with Sodium. M. W. Chase. (Am. Chem. Journ., Sept. 1909; 5 pp.) Some laboratory experiments to determine the heat of formation of titanium oxide and the method employed. 60c.

STONE

9554—MARBLE PROSPECTS IN THE Chiricahua Mountains. Arizona. Sidney Falke. (Bull. No. 380, U. S. Geol. Surv., 1909; 15 pp.) Notes on the geography, topography and geology of the marble deposits in southeastern Arizona. Illustrated. 20c.

9555—ROCKY MOUNTAIN REGION—The Building Stone of the Rocky Mountains. Arthur Lakes. (Min. Sci., May 6, 1909; 14 pp.) An article dealing with the many kinds of building stone which occur in the Rocky Mountain region, together with notes on their availability and use. Illustrated. 20c.

TIN

9556—ALASKA—Some Features of the Alaskan Tin Deposits. Adolph Knopf. (Econ.

Geol., April, 1909; 10 pp.) Notes on the tin deposits of Seward peninsula, and outline of the general and economic geology. 60c.

9557—ALASKA—York Tin Mines. J. H. Hill. (Northwest Min. Journ., Mar., 1909; 1 p.) A short historical review of the prospecting and development of the placer tin deposits of Seward peninsula, Alaska. 20c.

9558—CORNWALL—Some Cornish Mines and Their Associated Works. Leonard C. Bick. (Cumberland Govt. Min. Journ., Mar. 15, 1909; 2 1/2 pp.) A description of the Botallack mine and mill; also Wheal Bassett, South Crofty and Port Lidden mills. Illustrated. 40c.

9559—SOUTH DAKOTA—Tin in the Black Hills of South Dakota. Jesse Simmons. (Min. Wld., May 15, 1909; 1 1/2 pp.) A short historical review of tin mining in the Black Hills, with notes on the geology of the district and the operations of the Harney Peak Company. Illustrated. 20c.

9560—TASMANIA—Mount Bischof Tin Mining Company. Tasmania. J. D. Miller. (Aust. Min. Stand., Mar. 10 and 17, 1909; 4 pp.) A description of the hydro-electric power plant, its equipment and operation. Illustrated. 60c.

TUNGSTEN

9561—COLORADO—Tungsten in Colorado. H. R. Vose. (Quart. J. Geol. Soc. Sch. Min., 1909; 36 pp.) A description of the tungsten deposits in San Juan and Boulder counties, Colorado. Notes on the physical properties, mineral uses, metallurgy and alloys of tungsten. Illustrated. 20c.

9562—COLORADO—Tungsten Industry of Boulder County, Colorado. In 1908. R. H. George. (Eng. and Min. Journ., May 22, 1909; 1 p.) Includes a description of the conditions in this district, accompanied by a map showing the location of the producing mines and prospects. 20c.

9563—MAGNETIC SEPARATION—Notes on the Magnetic Separation of Tungsten Minerals. Henry E. Wood. (Proc. Colo. Sci. Soc., April, 1909; 5 pp.) A description of a system of magnetic separation which is claimed to have many advantages over wet concentration. It is applicable only to wolframite. 20c.

9564—MINING AND MILLING—Tungsten Mining and Milling. Victor G. Hills. (Proc. Colo. Sci. Soc., April, 1909; 20 pp.) A description of the tungsten deposits in Boulder county, Colorado, together with notes on mining and milling. Illustrated. 20c.

ZINC

9565—JOPLIN DISTRICT—Migrations of the Joplin Zinc Belt. Charles R. Keyes. (Eng. and Min. Journ., May 22, 1909; 1 p.) A discussion of the migrations of the Joplin orebodies together with notes on the later geologic history. 20c.

9566—LEAD AND CADMIUM IN SPELLER—Determination of Lead and Cadmium in Spelter. Eric John Erlson. (Eng. and Min. Journ., May 22, 1909; 1 p.) A method for the accurate determination of lead and cadmium at the same time giving a separation for cadmium. Also notes on cadmium determination. 20c.

9567—NEW MEXICO—The Tres Hermanas Mining District, New Mexico. Waldemar Lundgren. (Bull. 380-C, U. S. Geol. Surv., 1909; 10 pp.) See under "Lead."

9568—SHEET ORE MINING—Departure in Sheet-ore Mining in the Joplin District. Tony J. Chapman. (Eng. and Min. Journ., May 8, 1909; 1 p.) A short description of the method of sheet ore mining as employed at the Red Dog mine, Joplin, Mo. Illustrated. 20c.

9569—WISCONSIN—Mining Laws and Lease System in Wisconsin Zinc District. J. E. Kennedy. (Eng. and Min. Journ., April 24, 1909; 1 p.) A discussion of the mining laws of Wisconsin, including coverage, rights, conflicting claims, and general provisions of leases. 20c.

ECONOMIC GEOLOGY—GENERAL

9570—ARIZONA—Minerals of Arizona. W. P. Blake. (Transactions, 1909; 64 pp.) A report by the Territorial Geologist to the Governor of Arizona on the occurrence of various minerals of the Territory, with notes on their composition.

9571—GASTRIER—In Bluff County, Penn. See under "Charles Butts." (Bull. No. 380-J, U. S. Geol. Surv., 1909; 5 pp.) Notes on the geology, methods of exploitation and location of gambler deposits.

9572—MASSACHUSETTS—The Lead and Silver Deposits at Newburyport, Massachusetts, and Their Accompanying Contact Zones. C. H. Cripp and W. G. Hall. (Econ. Geol., April, 1909; 12 pp.) Notes on the history, topography, general geology, ore deposits, con-

tact zones, and the origin of the minerals and ores. 60c.

9573—NEW HEBRIDES ISLANDS—Mineral Possibilities of the New Hebrides Islands. G. M. Colvocoresses. (Eng. and Min. Journ., May 8, 1909; 1 p.) A description of the principal mineral deposits of the New Hebrides with special reference to the sulphur deposits. 20c.

9574—NEW ZEALAND—Outline of New Zealand Geology. James Park. (N. Z. Mines Rec., 1909; 16 pp.) 1909. 31 pp. Historical review of the work of the Geological Survey and a general description of the physiography of New Zealand. The second chapter deals with the general geological structure of New Zealand, glaciation and the classification of the sedimentary formations. 60c.

9575—ORE DEPOSITION—Locus of Vadoso Ore Deposition. Charles R. Keyes. (Eng. and Min. Journ., Apr. 24, 1909; 1 p.) A discussion of the zinc and lead deposition of the Quark region, and their connection with vadoso accumulations. 20c.

9576—ORE DEPOSITS—Occurrence of Ore Deposits in Mineral Belts. Arthur Lakes. (Min. Wld., Apr. 10, 1909; 2 1/2 pp.) A discussion of the geology of mountain ranges and of the causes and faulting due to uplifts. Illustrated. 20c.

9577—ORE OCCURRENCE and Origin of Cave Mines. Arthur Lakes. (Min. Wld., Apr. 17, 1909; 2 pp.) Some notes on caves and their origin in the various minerals. Also found in them and a short description of some of the principal caves in the Silverton and Ouray districts, Colorado. Illustrated. 20c.

MINING—GENERAL

9578—ALASKA—Transportation Facilities in Alaska and the Yukon. W. M. Brewer. (Min. and Sci. Press, Apr. 3, 1909; 2 1/2 pp.) The author gives a description of a number of the principal lines of communication from Seattle to various Alaskan points. He also gives notes on the present status of the railroad construction and mileage in Alaska. Illustrated. 20c.

9579—ARIZONA AND CALIFORNIA—Mining in Western Arizona and Eastern California. W. A. Root. (Min. Wld., May 15, 1909; 3 1/2 pp.) A description of the mining operations near Parker, Arizona, with a short description of a number of the principal mines. Illustrated. 20c.

9580—AUSTRALIA—Twenty-Five Years of Mining. Edward Ashmead. (Min. Journ., Apr. 17 and May 1, 1909; 3 1/2 pp.) A retrospective review from 1880 to 1904 of mining companies registered in Great Britain, with notes and comments and the names and initials of the principal registrars. These articles deal especially with Western Australia and Tasmania mines. 60c.

9581—CHINA—Mining in Northern China. F. L. Cole. (Min. and Sci. Press, Apr. 24, 1909; 10 pp.) A short history of the mining industry in Northern China, with some notes on securing mining rights from the Government. 20c.

9582—CALIFORNIA—Economic Conditions in California. F. Lynwood Garrison. (Min. and Sci. Press, Apr. 17, 1909; 3 pp.) Notes on climate, mining laws, land titles and labor conditions, as existing in the United States of California. 20c.

9583—COMPRESSED AIR—The Measurement of Compressed Air. J. Orr. (Journ. Transvaal Inst. Mech. Engrs., March, 1909; 19 pp.) Notes on the methods used for measuring compressed air for estimating the consumption of air by the various drills in the Transvaal stone drill competition. Illustrated. 60c.

9584—DEEP LEVEL MINING—Suggestions for Modern Deep Level Mining. H. H. Johnson and H. F. Roche. (Journ. S. Afr. Min. Assn. Engrs., March, 1909; 15 pp.) Notes on the surface equipment for deep level mining with special reference to head gear, crushing and sorting station, mill, transportation of ore and administration. Illustrated. 80c.

9585—DIAMOND DRILLING—Deep Diamond Boring at Balfour Mines, Fifeeshire. James G. Thomson. (Trans. Min. Inst. Scot. Vol. XXXI, Part 4, 1908; 7 pp.) A description of the diamond boring plant and its operations during the process of putting down a bore hole at Balfour Mines, Great Britain. Illustrated. 20c.

9586—DRILLING—Air Economy in Rock Drills. Alexander Macdonald. (Eng. and Min. Journ., May 1, 1909; 1 p.) A comparison of a series of tests of the Komatsu and 3 1/2-inch piston drill with reference to the amount of air consumed during the operation. Illustrated. 20c.

9587—FLOW OF WATER IN Flumes or Launder. R. F. Neale. (Trans. Engr. Apr. 20, 1909; 1 1/2 pp.) These notes apply not only to the water courses, but also refer to artificial flumes, such as those con-

structed to carry water in irrigation or for hydraulic purposes. Illustrated. 20c.

9588—HOISTING—Counterbalanced Hoist. R. L. Hays. *Eng. and Min. Journ.*, May, 1909; 2½ pp. Examples of ingenious devices used in Colorado mines which result in great economy of power. Illustrated. 20c.

9589—IDAHO—Mining Laws of the State of Idaho. Compiled by F. Cushing Moore, State Inspector of Mines. (Boise, Ida., 1909; 3 pp.) Extracts from the Constitution, the Revised Codes and the Session Laws of Idaho. Relative to Mining.

9590—JAPAN—The Mining Industry in Hokkaido, Japan. (Min. Journ., April, 1909; 2 pp.) Statistics relating to the applications for mining leases, the mines and their area; general conditions of work; washeries; wages; output; accidents and casualties. 40c.

9591—MARYLAND—The Mineral Production of Maryland in 1908. W. J. Clark. (Eng. and Min. Journ., May 1, 1909; 1 pp.) Gives statistics of the production of coal, building stone, clay, lime and cement, sand and gravel, flint, etc. 20c.

9592—MEXICAN MINING LAW—Protection of Mexican Miners. F. J. J. Merrill. (Min. and Sci. Press, Apr. 3, 1909; 2 pp.) A discussion of the Mexican mining code with special reference to the titles to mining property. 20c.

9593—MINE ACCOUNTING—The Auxiliary Books in Mine Bookkeeping—II. Matt W. Alderson. (Min. and Sci. Press, Apr. 10, 1909; 2 pp.) The second of a series of articles on mine bookkeeping in which the author takes up the forms and methods of keeping mine and mill reports. 20c.

9594—MINE ACCOUNTS for the Superintendent. Harold Wilson. (Min. and Sci. Press, May 15, 1909; 1½ pp.) Notes on mine and mill forms as used by the North Pole Mining Company, Colorado. 60c.

9595—MINING GAS—The Estimation of Carbon Monoxide in Mine Gases. H. Welskopf. (Journ. Chem., Met. and Min. Soc. of South Africa, Feb., 1909; 8 pp.) In this article the author gives a method for the determination of the percentage of gas from the products of explosion; the estimation of carbon monoxide and the calculation of the results obtained and their practical application. 60c.

9596—MINE REPORTS—Geologic Essentials of a Mine Report. C. DeKalb. (Min. and Sci. Press, May 1, 1909; 4 pp.) An address delivered before the Geologic Society of Stanford University, in which the author discusses problems of geology and economics of mining. 20c.

9597—NEW MEXICO—Mines of the Lordsburg District, New Mexico. J. A. W. (Eng. and Min. Journ., May 1, 1909; ¾ pp.) A short description of a number of the principal mines in the Lordsburg district. 20c.

9598—PROSPECTING—From Prospect to Mine. Etienne Remy. (Sci. May 15, 1909; 3 pp.) The first of a series of articles on prospecting and mining. This article gives special attention to the methods of prospecting for and discovery of mineral. Illustrated. 20c.

9599—QUEENSLAND MINING INDUSTRY. (Queensland Govt. Min. Journ., April, 1909; 16 pp.) Advance copy of the annual report of the Under secretary for mines in the Queensland mining industry for the year 1908, giving statistics of production. 60c.

9600—SHAFT SINKING—Modern Shaft Sinking. Francis Donaldson. (Min. and Sci. Press, April, 1909; 2 pp.) Continuation of the article previously indexed. Description of the plant required; hoilers, hoisting engines, head frames, buckets, air compressors, etc., together with notes on contract forms and specifications. Illustrated. 20c.

9601—SHAFT SINKING—Note on a Problem During Shaft Sinking. C. R. Sauer. (Journ. Chem., Met. and Min. Soc. of South Africa, March, 1909; 2½ pp.) Method used in shaft sinking on the Rand where a large amount of water was encountered. Illustrated. 60c.

9602—TIMBER PRESERVATION—Open Tank Method of Preserving Timber. Howard F. Weiss. (Eng. and Min. Journ., Apr. 21, 1909; 1½ pp.) Notes on the seasoning of wood, the absorption of preservative and the cost of different sizes of open tank plants. 20c.

9603—TONNAGE ESTIMATION IN PUMPS—Open-cuts, etc. B. H. Cas. (Eng. and Min. Journ., May 15, 1909; 1 p.) Method used by the author at the Barton zinc mines in 1890-91. 20c.

9604—TOPOGRAPHIC ENGINEERING—W. D. Blackburn. (Eng. and Min. Journ., May 15, 1909; 1 p.) Notes on the application of engineering with special reference to the application in geological and mining work. 20c.

9605—TUNNELING—Driving Headframes and Rock Tunnels. W. L. Stone. (Eng. and

Min. Journ., April, 1909; 27 pp.) A description of tunnel driving, methods and machinery employed. Notes on American and European tunnel records. Illustrated. 40c.

9606—TUNNELING—Methods and Cost of Tunneling on the Alaskan-Central Railway. G. A. Kyle. (Eng. Con., Apr. 7, 1909; 6 pp.) Tabulated results showing progress, contract prices, cost of explosives, equipment, wages and total cost. 40c.

9607—TUNNELING—Rapid Methods in Driving Alpine Tunnels. Walter I. Alms. (Eng. Con., Apr. 28, 1909; 1½ pp.) Notes on the method of tunnel work as employed in the Alps, where records have far exceeded those in America. Illustrated. 20c.

9608—TUNNELS—Experience with Long Trench Tunnels. Arthur Lakes. (Min. and Sci. Press, Apr. 15, 1909; 2 pp.) Discussion on the advantages and disadvantages in long tunnels, crosscutting rock formations to veins outcropping on the surface. Illustrated. 20c.

9609—VALUATION OF MINES—The Computation of the Present Value of Developed and Undeveloped Mines. W. H. Goodchild. (I. M. S. Bull. No. 55, Apr. 15, 1909; 10 pp.) A discussion of the methods of valuation together with some notes on capitalization. 60c.

9610—WESTERN AUSTRALIA—Mining in Western Australia. (Aust. Min. Stand., Mar. 1, 1909; 1 p.) Some notes on the graphite deposits in the Great Boulder mine with general notes on the operations of the principal mines in the Kalgoorlie district. 40c.

9611—WINDING—STRESSES on Winding and Conducting Ropes as used in Mine Shafts. Joseph Hindley and John Stoney. (Trans. Manchester Geol. and Min. Soc., Vol. XXXI, 1908-1909; 7 pp.) A short mathematical discussion of stresses in winding ropes with some notes on an indicator for ascertaining the stresses. Illustrated. 40c.

ORE DRESSING

9612—CONCENTRATION—Calculations in Ore Concentration. Rudolf Gahl. (West. Chem. and Met., April, 1909; 19 pp.) Notes on the value of assays, screen tests, distribution of pulp, together with some calculations as to ore concentration. Illustrated. 80c.

METALLURGY—GENERAL

9613—ELECTROLYTIC RECOVERY of Metals from Ores. J. H. Jorg. (Min. and Sci. Press, May 8, 1909; 1½ pp.) A description of an electrolytic sluice as employed for amalgamation together with notes on its operation. 20c.

9614—JAMESONITE ORE TREATMENT—Metallurgical Treatment of Jamesonite Ores. G. P. Ives and I. D. Ossa. (Eng. and Min. Journ., May 1, 1909; 1 p.) Notes on the treatment and smelting of jamesonite ores, and the electrolytic refining of lead. 20c.

9615—METALLOGRAPHY—Polishing for Examination with the Microscope. Albert Kingburg. (Journ. A. S. M. E., May, 1909; 4 pp.) Notes on methods used for polishing steel to be used when high magnification is required in metallographical work. 20c.

9616—MILL BUILDINGS—Salient Points in Steel Mill Buildings. J. H. Heston. (Industrial Engineering, April, 1909; 4 pp.) A discussion of the design of mill buildings with reference to strength, durability and lighting. Illustrated. 40c.

9617—SMELTER SMOKE—Local Status of Works Producing Noxious Gases. Charles Taskerville. (Eng. and Min. Journ., May 1, 1909; 1½ pp.) A discussion of the different phases of the smelter smoke problem in the United States, together with notes on the Lucknow, Anaconda and Contra Costa cases. 20c.

MINING AND METALLURGICAL MACHINERY

9618—AIR COMPRESSOR TESTS. W. A. Macleod and J. P. Wood. (Proc. Aust. Inst. Min. and Metall., 1909; 3 pp.) Continuation of a previous paper and gives additional indicator cards indicating the performance of a machine after 15 months of continuous running. Illustrated. 20c.

9619—BOILER WATER—Feed Water Heaters as Purifiers. J. C. William Greth. (Industrial Engineering, April, 1909; 8 pp.) Heat and loss relation in the use of boiler water for industrial uses, especially boiler feed, is discussed, together with tabulated results of laboratory experiments. 40c.

9620—BOILER WATER—The Automatic Purification of Boiler Waters. W. A. Macleod. (Eng. News, May 20, 1909; 1 p.) A description of a scheme which permits of continuous work with an automatic purifier approximating that given by a detailed test by ordinary methods. 20c.

9621—CONVEYERS—Transporters, Elevators and Conveyors. Edward Butler. (Eng. and Min. Journ., April, 1909; 1 p.) Continuation of a previously indexed. The author here discusses the single and double chain auto-

matic grabs, and gives a number of illustrations showing their mechanical construction. 40c.

9622—CONVEYING MACHINERY—A Unique Belt Conveyor. E. C. Soper. (Journ. A. S. M. E., May, 1909; 5 pp.) A description of a belt conveyor one quarter of a mile long used for the handling of Portland cement material. Illustrated. 40c.

9623—CONVEYING MACHINERY—Automatic Feeders for Handling Material in Bulk. C. Kemble Baldwin. (Journ. A. S. M. E., May, 1909; 9 pp.) This paper presents a brief description of the various types of automatic feeders now in use including the undercut-grate, lifting gate, screw conveyor, roll and plunger feeders. Illustrated. 40c.

9624—CONVEYING MACHINERY—Mechanical Appliances Used on the Mines of Western Australia. W. G. Manners. (Monthly Journ. W. A. Chamber of Mines, Feb. and Mar., 1909; 9½ pp.) Notes on the transportation of material by mechanical means, with special reference to launders, rope haulage and belt and push conveyors. Illustrated. \$1.40.

9625—CONVEYING MACHINERY—Modern Material-Handling Machinery for Industrial Plants. (Journ. A. S. M. E., Eng., April, 1909; 26 pp.) A discussion of chain blocks, derricks, I-beam systems, traveling cranes, locomotive cranes, with some notes on coal storage systems. Illustrated. 40c.

9626—ELECTRIC POWER PLANT—Electrical Devices in Modern Mining. (Eng. Journ. of Canada, Apr., 1909; 1 p.) A description of the plant of the Copper Cliff mine, Canada, at which electricity is extensively employed to the extent of over 5000 horsepower. 20c.

9627—FUEL ECONOMIZERS—Eliminating Waste in Steam Generation. Carl St. John. (Industrial Engineering, April, 1909; 7 pp.) A discussion and description of the Sturtevant economizer and the Green fuel economizer. 20c.

9628—GAS POWER—The Value of Gas Power. Charles E. Lucke. (Can. Engr., Apr. 23, 1909; 5 pp.) A discussion of the efficiency of gas engines; notes on producer gas together with notes on the cost of power and power plants. 20c.

9629—GAS PRODUCER PLANTS—Suction Gas Producer Plants and Their Application in South Africa. H. W. Miller. (Journ. Transvaal Inst. Mech. Engrs., March, 1909; 22 pp.) A detailed description of the suction gas producer plant, and analyses of South African coals. Also notes on the utilization of gas for engine driving. Illustrated. 60c.

9630—HYDRO-ELECTRIC PLANTS—The Design of Steel Pipes for Hydro-Electric Plants. Richard Muller. (Eng. Rec., May 1, 1909; 1½ pp.) A mathematical discussion of the design of steel water pipes to be used under heavy pressure. Illustrated. 20c.

9631—LIQUID FUEL BURNING ARRANGEMENTS for Steam Boilers. (Electrochem. and Met., and May, 1909; 1½ pp.) Notes on high efficiency combustion, and illustrations of several arrangements for burning liquid fuel in steam generators. Illustrated. 20c.

9632—POWER TRANSMISSION—Leather Belting and Rope Drives Compared. (Eng. Journ. of Canada, Apr., 1909; 3 pp.) A discussion of conditions under which both forms of drives should be employed. A practical consideration of the problem which is the best general form of drive. 20c.

9633—PRODUCER GAS—The Combustion of Producer Gas. Oskar Nagel. (Electrochem. and Met., and May, 1909; 1½ pp.) Notes on high efficiency combustion, the richness of gas-air mixture and preheating of the air. 40c.

9634—PUMPS—Centrifugal Pump Efficiency. V. V. Messer. (Min. and Sci. Press, May 15, 1909; 2½ pp.) Notes on the construction, cost and efficiency of centrifugal pumps. Illustrated. 20c.

9635—PUMPS—Electrically Operated Centrifugal Pumps. In Belgium. Frank J. Perkins. (Min. and Sci. Press, Apr. 2, 1909; 2 pp.) A description of the type, construction and pressure of pumps driven by electric power. Illustrated. 20c.

9636—PUMPS—Sinking Pumps. Frank S. Mitchell. (Journ. Assn. Eng. Soc., March, 1909; 4 pp.) A short description of a sinking pump in which the inventor endeavors to have the minimum weight, giving a continuous flow in one direction by means of a differential plunger. Illustrated. 40c.

9637—PYROMETER—The Related Recording Pyrometer. Percy Longmuir and Thomas Swinden. (Iron and Steel Institute, May, 1909; 12 pp.) Notes on the installation of pyrometer and tests to ascertain the behavior of pyrometer under normal working conditions in hot blast furnaces. Illustrated. 20c.

Industrials

The Pneumelectric Machine Company, of Syracuse, N. Y., has established a new agency with Eastin & Haley, in the Madisonville Savings Bank building, Madisonville, Ky.

Traylor Engineering Company, Allentown, Penn., reports that it has just closed an order with the Boston Idaho Mining Company, of Boston, Mass., for a 100-ton concentrating plant.

It is reported that the Berwind-White Coal Mining Company, Windber, Penn., has installed four more Pneumelectric coal punchers. This brings the total up to twenty-six now in use by this company.

Du Bois Iron Works advises that its office, formerly located at 1206 Park building, Pittsburgh, Penn., and managed by G. E. Webb, has been moved to 1429 Park building, giving more commodious quarters.

The John Simmons Company, 102 Centre street, New York City, has about perfected the new Baldwin acetylene safety lamp. It is constructed on lines as simple as the regular models and is also about the same size and weight as the present type of safety lamp.

The C. O. Bartlett & Snow Company reports the following recent orders: Benson Mines Company, Benson Mines, N. Y., one skip hoist; Geo. H. Clippert & Bro. Brick Company, Detroit, Mich., one low-pressure brick dryer, capacity 30,000 brick per day; Baldwin Bros., Cleveland, Ohio, one gravel outfit for disintegrating, elevating, screening and washing gravel.

A report has been circulated that the Ottumwa Iron Works, Ottumwa, Iowa, has been totally destroyed by fire. This report probably originated from the burning of the foundry roof. The damage has, however, not only been repaired, but the foundry has been enlarged and improved machinery added to increase the output and the quality of the product of the company.

The C. O. Bartlett & Snow Company announces that owing to the increased eastern business of the company, it has established an office at 50 Church street, New York City, in charge of H. H. Bighouse, chief engineer, who will give personal attention to all matters pertaining to the elevating, conveying and economical handling of materials, as well as mechanical drying and other lines of the business.

Chalmers & Williams, Inc., Chicago, Ill., report the following sales: Five stamp mill to M. K. Rodgers, Alaska; No. 5 Kennedy gyratory crusher, two sets of 36-in. by 14-in. rods and twelve 6-ft. cone vanners to Bunker Hill and Sullivan Milling and Construction Company; 34-ft. Huntington mill plant for Cape Graecias, N. C.; No. 6 Kennedy gyratory crusher, with screen and elevator, to Arthur McMullen and Company, New York City.

Asa Whitney, formerly of A. Whitney & Sons' Carwheel Works, Philadelphia, who has been for some years secretary and metallurgist of the Sanford-Day Iron Works, Knoxville, Tenn., has severed his connection with that company and will engage in the manufacture of mine equipment and car wheels at Bristol, Tenn. Mr. Whitney is a grandson of Asa Whitney, a pioneer in the manufacture of chilled wheels and at one time president of the Philadelphia & Reading Railway.

Penberthy Injector Company, Detroit, Mich., offers to send sample copy of "The Penberthy Engineer and Fireman" free. The subscription price is 50 cents a year, including a handsome silver-finish watch fob premium. The magazine does not write up the company or any other concern. Its circulation is 10,000 copies each month and it has over 3,500 paid subscribers, contains 80 pages of choice, interesting, instructive reading. Handsome cover and good quality paper throughout.

Circular 1502 issued by the Westinghouse Electric and Manufacturing Company contains much valuable information on alternating

current distribution covering transformers, lighting arresters, insulators, cross arms, etc. Considerable space is devoted to underground and overhead construction applicable to congested and scattered districts. There is also given information on potential regulating systems. The circular contains 52 pages of information of value to any central station man or any other connected in any way with the distribution of power by alternating current lines.

Since the appearance on the market of ready roofings that need no painting, there has been a very lively curiosity on the part of many people to see the goods. Accordingly the makers of Anattite have arranged to supply samples to any inquirer free of charge. These samples show the goods complete with the mineral surface which replaces paint as a protection against the weather, and it is easy to obtain a very good idea of just what Anattite is like. All you have to do in order to obtain the sample is to send a postal card request for same to the nearest office of Barrett Manufacturing Company, at New York, Chicago, Philadelphia, Boston, Cincinnati, Cleveland, Pittsburgh, Minneapolis, St. Louis, Kansas City or New Orleans.

Footo Mineral Company has issued the fifteenth edition of its complete mineral catalog, compiled by W. M. Footo. This notable compend is of permanent value to the field amateur, as well as the professional mining man. The present volume has been completely overhauled by the compiler from cover to cover and embodies an inexhaustible fund of information relative to metalliferous minerals, including important data on the rare metals which intuitively appeal to the student and all around mining man. The work adheres closely to the Dana system and the different types and varieties follow each species heading with more elaborate descriptions of the forms and physical characters of each than was practical in earlier issues. The catalog will prove a useful addition to the industrial library of the professional worker.

A large installation of squirrel-cage induction motors, aggregating 2200 h.p., is being made at the Bonnie Cotton Mills, Kings Mountain, N. C. These motors, which have been furnished by the Crocker-Wheeler Company, of Amper, N. J., will operate on a 2080-volt, 3-phase, 60-cycle circuit. There are 32 machines in all, varying in output from 20 to 100 h.p. Each unit is controlled from a separate panel, built of Blue Vermont marble. Two 10-kw., 2200 110 volt-Crocker-Wheeler transformers will also be installed in this plant. The Youngstown Sheet and Tube Company, Youngstown, Ohio, has added to its 5000 h.p. of Crocker-Wheeler motors by installing a 500-h.p. synchronous motor. This machine will operate on a 3-phase, 25-cycle circuit at the unusually high potential of 6000 volts. It will be used to drive a centrifugal pump. The Indiana Steel Company, Gary, Ind., has placed an order for twenty-one Form W motors, aggregating 655 h.p., of the type developed by the Crocker-Wheeler Company for rolling-mill service. These machines will be used to operate cranes on a 220-volt, direct-current circuit.

A. Leschen & Son Rope Company has just issued a very handsome book of views, entitled "Over the Waters of Lake Michigan." The various views in this pamphlet show the construction and arrangement of the Leschen Company's patent friction grip wire rope tramway furnished to the George W. Jackson, Inc., Chicago, Ill. The tramway is 8000 ft. long and, with the exception of a few hundred feet, is built over Lake Michigan—connecting a temporary crib out in the lake with the shore. The tramway is used to transport rock and other material excavated in the construction of the new water supply tunnel for Chicago. The excavated material is elevated through a shaft in the crib out in the lake and is then loaded into the tramway carriers or buckets. At the land terminal

the rock is discharged into bins, where it is later crushed for the making of concrete. The workmen go to and from the crib over the tramway in specially designed carriers. The carriers hold an average of 1000 lb. of material each and are fitted with a patent friction grip, whereby each carrier is automatically released from the rope on entering a terminal station. By means of a series of overhead rails it is possible to move the carriers to any desired point for loading or discharging. The gripping of the carriers to the rope is performed mechanically. The power necessary to operate the system is applied through bevel gearing at the shore terminal.

Trade Catalogs

The Engineering and Mining Journal

VOL. LXXXVII.

NEW YORK, JUNE 12, 1909.

NO. 24.

Foundations of the Goldfield Consolidated Mill

About 7000 Cubic Yards of Concrete in Place Cost \$11.82 per Yard,
The Average Mixture Being 1—3.6 — 3.67. Labor Cost High

BY PERCY E. BARBOUR*

The new 600-ton mill of the Goldfield Consolidated Mines Company at Goldfield, Nev., which has recently been put in operation, presents an example in the matter of concrete foundations in metallurgical mill construction, that is notable

6182 yd. of which are here given. The steel-mill building weighs 1,453,304 lb. and the machinery and equipment resting on the concrete will weigh as much more, not including the pulp in process in the tank, which will be 600

the mill was in hand, it was estimated that the concrete would cost \$12 per yd. in place. Detailed cost sheets for 6182.7 yd. show an actual total average cost of \$11.82 per yd. of concrete in place, which is certainly a lasting compliment to

THE GOLDFIELD CONSOLIDATED MILL, ABOUT TWO MILES NORTH OF GOLDFIELD, NEV.

MILLSITE, SHOWING CONCRETE PLANT AND GRAVITY TRAM—GOLDFIELD CONSOLIDATED MINES COMPANY

in several ways. The size of the job is not the least interesting of the data to be given in this connection. In excavating for the mill foundations, 28,325 cu.yd. of rock were blasted. Nearly 7000 cu.yd. of concrete have been placed, data on

tons of ore per day with treatment water amounting to 6 tons of water to the ton of ore. In addition to this, the battery ore bins when full hold 4000 tons of ore.

The equipment of the mill and the plan of treatment were described in the *Journal* of Sept. 5, 1908. When the design of

J. H. MacKenzie, general manager, and to J. B. Fleming, the mechanical engineer, under whom the original design was made.

CONCRETE PLANT

The mill is of the usual terraced construction and is situated about 2 miles

*Mining engineer, Los Angeles, Cal.

down of Goldfield. At the top of the hill was the plant for crushing the rock and making the concrete. This plant consisted of a No. 3D Gates gyratory crusher, set to give a 2½-in. product. From this crusher the rock was carried by a steel-wire bucket elevator to a 48x84-in. revolving screen which ran 21 r.p.m., and was set with a pitch of 1¼ in. per foot. The oversize from this screen was discharged directly into a storage bin below. The product through the screen was passed through a set of 26x15-in. style A Allis-Chalmers rolls set directly below the screen. These rolls were set for a ½-in. product. This fine product, much of which would pass a 16-mesh screen, was used for sand in the concrete and was discharged from the rolls into a second compartment of the storage bin below. The crushing plant was driven by a 75-h.p., 3-phase, 440-volt, 60-cycle, Bullock motor.

The rock to be crushed was hauled to the top of the hill by two- and four-horse teams and was dumped on a platform level with the hopper of the gyratory crusher,

sand used was a product from the crushing of this rock. The rest of the sand was dug from various deposits found in the adjacent desert and was also free. Little good sand can be found for concrete purposes near Goldfield, as it contains such a large proportion of volcanic ash that it would make poor concrete. All of the pit sand used was dumped into the big crusher, although only rarely were there any rocks or pebbles large enough to be broken. It was then elevated to the screen, and thence to the rolls and thus brought to size.

Hauling the rock from the quarry to the concrete plant was done by contract teams. A two-horse team was paid \$8.50 per day and hauled 1 yd. at a load. A four-horse team was paid \$14 per day and hauled 3 yd. at a load. In either case eight loads were required as a day's work. The total amount of rock quarried was 6267.4 yd., of which there was used in the concrete 3842 yd. of crushed rock, the balance being used as rock sand. In the lower portion of three

the first and the last foundations is about 132 ft., and the horizontal distance between the two is 395 feet.

The retaining walls and piers for building columns are designated by letters beginning *A, E, F*, etc., to and including *L*. *B* and *C* are rows of piers for intermediate columns under the ore bins; *D* is the concrete mortar block. All the retaining walls and foundations which carry building columns are 2 ft. wide on top; the back of the wall is in each case vertical and the front wall has a batter of 1½ in. per foot.

Beginning with wall *E*, all walls are reinforced with Johnson reinforcing bars of ¾-in. corrugated steel. Wall *A* is a plain low retaining wall; *B* and *C*, as already stated, were for ore-bin columns. The sampling-mill foundations were plain low walls and joined the main mill at the south end of the ore bins. The battery block *D* is an interesting block of concrete construction. It is 192 ft. to in. long by 6 ft. wide on top and has a cross-sectional area of 96 sq. ft. Instead of

FORM FOR RETAINING WALL F

CONCRETE FOUNDATIONS—GOLDFIELD CONSOLIDATED MILL

into which it was shoveled by hand. The rock and sand were drawn from the storage bin through standard rack-and-pinion ore gates into Sterling concrete buggies on the mixing platform, which was about 10 ft. wide. From these buggies it was dumped into a No 2 Ransome mixer of ½ yd. capacity. This mixer was driven by a separate 10-h.p. motor. Cement was brought to the mixing platform from the storehouse by a short semi-gravity inclined tramway about 175 ft. long, operated by a small electric hoist. Concrete buggies receiving the mixture dumped it into a short chute leading to a skip car underneath the platform. This skip was one of two on an inclined gravity tramway which lowered the mixture to the wall that was to be poured.

ROCK AND SAND

The rock for the concrete was quarried about 1½ miles from the mill on a privately owned and hence cost nothing except for the quarrying, hauling and erecting. The larger proportion of the

of the larger walls, large coarse rocks were embedded in the concrete.

FOUNDATIONS

The concrete used in the foundations required 1045.7 cu.yd. of cement, the average mixture of cement, sand and rock being 1—3.6—3.67 respectively. The mixture used in some of the individual walls may be of interest. For the low retaining wall *A*, the mixture was 1—2.7—3.96; for the battery block *D*, it was 1—3.14—3.14; the mixture 1—4—4 was used for the sampling mill and mill foundations *B* and *C*, retaining walls *I, J, K*, foundation piers *L*, and for certain of the tank foundations. The mixture for the tube mill foundations was 1—3.67—3.67, being almost identical with the average mixture of all concrete used.

The gravity tram was located on the center line of the mill, the shortest wall of which was 210 ft. long and the longest 294 ft. There were twelve walls and rows of foundation piers exclusive of the piers for machinery and tanks. The difference in elevation between the top of

anchor bolts set solidly in the concrete mass, rods were used for holding down bolts and subsequently inserted in 2-in. pipes which were set in the concrete in the usual way. Wide and deep apertures were left for the nuts and washers on the lower end. The thin webs between these apertures are each reinforced with two ¾-in. steel bars 3 ft. long. Wall *G* when constructed had a form for its face only. The back wall was built up of dry rubble as an experiment, which was not so satisfactory in saving of expense as to prompt a repetition. Piers *L* were building-column piers, 2 ft. square on top with the regular batter and from 12 in. to 2 ft. deep, to reach to bedrock.

The tube-mill foundations were the usual piers for the pillow blocks for the tube mills and the necessary main line shafting for driving them and are very heavy on account of the severe service imposed. The foundations for tanks consisted of straight walls 12 in. wide on top, both sides having a batter of 1½ in. per ft., and were from 12 in. to 4 ft. high depending on the nature of the

ground. Their only purpose was to furnish level, uniform supports for the timbers which were placed 24 in. apart, immediately under the wooden-tank bottoms.

Costs

The cost per yard of concrete in place for the retaining walls varied from \$10.05 to \$12.27, the latter figure being for the retaining wall *F* and the former for the retaining walls *I* and *J*. The battery

COST OF CONCRETE IN PLACE

Cement	\$5.03
Rock	1.06
Rock-sand	\$0.67
Pit-sandl.	0.45
Sand total cost.....	1.12
Labor	1.32
Forms	2.76
Engineering and Superintendence...	0.15
Reinforcing.....	0.38
Total cost per yard.....	\$11.82

tram cars to the forms was 35¢. per yd., but varied between 25 and 85¢, the latter figure applying on the small foundation piers L. The longest wall was 294 ft., making the wheel from the gravity tram cars 147 ft. Tamping cost varied between 31¢ and \$1.20, the average expense being 72¢. per yd. of concrete laid. With the high cost of Goldfield labor, these labor items are all very high and it should be noted do not include any

SECTION AND ELEVATION OF CONCRETE BATTERY BLOCK—GOLDFIELD CONSOLIDATED MILL

PROFILE OF MILL FOUNDATIONS- GOLDFIELD CONSOLIDATED MILL

block *D*, comprising 810 cu.yd. of concrete in place, cost \$11.60 per cu.yd. The tube-mill foundations cost \$12.65 per yd., and other foundations range from this figure up to as high as \$19.31 for some of the smaller blocks. The total average cost per yard of concrete in place was \$11.82, and is divided approximately as shown in the accompanying table. The item of reinforcing appears too high per yard in this table because it is apportioned over a somewhat larger number of yards than were actually reinforced. The proper cost per yard reinforced is 48 cents.

HIGH LABOR EXPENSE

The scale of wages for this job was high, as everything is in Goldfield, and was approximately as follows per 8-hour shift: carpenter 6 men, \$6; carpenters, \$5; carpenter helpers, \$4; concrete foremen, \$4; concrete laborers, \$3.50.

Under labor the expense includes a unit price of 25¢ per yd. for a work to cover the drawing of the crushed material from the bins, wheeling across the short platform, dumping into mixers, adding of cement and water, and running the motor. The average labor cost for raising the concrete from the gravity

labor in connection with the building and tearing down of the forms.

PREPARING THE FORMS

In building forms for the foundations some of the lumber was used several times, and on the average it could be used three times before destruction. The forms were made of 2-in. planks; the ties were 2x4 in. and the braces were of 4x4, 4x6 and 6x6 in. timbers. The forms for the higher walls were tied together by telegraph wire, twisted between the braces. All foundations bolts were hung in the usual way from cleats which

were wired at the bottom to keep them in the proper position.

The charge for engineering and superintendence includes the total time of a concrete superintendent, a civil engineer running a transit and a chairman, but does not include designing or drafting office expense. Power cost for running the crushing and mixing machinery was extremely low, owing to the efficient sys-

ported at 3,804,129 tons. This would indicate that considerable stocks of ingots must have been carried over from the previous year, or that some foreign material was used. The latter is more probable, as Great Britain was a large importer of billets and blooms last year, chiefly from Germany. For some periods of the year British mills could buy billets, forced on the market by the German Steel Syndicate, for less than it cost to make them in their own works.

The make of finished material from bessemer steel is not fully reported, bars, forgings and some other important items being omitted. More than half the bessemer steel was used in making rails. The total production of rails for two years was, in long tons:

	1907.	1908.	Changes
Bessemer steel.....	832,576	715,407	D. 117,169
Open-hearth.....	79,532	192,626	I. 112,993
Total.....	912,108	907,932	D. 4,176

The remarkable point here is the great increase in open-hearth steel rails, which points to a movement in their favor similar to that which has been going on in this country.

The production of wrought or puddled iron was in direct opposition to that of steel. For several years this output has been declining, but in 1908 it showed a large gain; advancing from 975,083 tons in 1907 to 1,168,115 tons in 1908, an increase of 193,032 tons, or 19.8 per cent. The reason for this change is not altogether clear. The total production of bars, plates and all other finished forms from wrought iron last year was 1,050,772 tons.

The Engineering & Mining Journal, N.Y.
REINFORCING BARS FOR RETAINING WALL F

tem of purchase and distribution of electricity by the company. The total average cost per horsepower-hour was \$0.009. The power was secured from the Nevada-California Power Company, being brought from Bishop, Cal., 150 miles west of Goldfield.

British Steel Production

As already noted, the production of pig iron in Great Britain in 1908 was 9,289,840 long tons; being a decrease, as compared with 1907, of 634,016 tons, or 6.4 per cent.

The British Iron Trade Association has now reported the production of steel for 1908, which shows a greater comparative decrease than that of pig iron, the total decline having been 1,227,106 tons, or 18.8 per cent. The make of steel for two years has been, in long tons:

	1907.		1908.
	Tons.	Per Cent.	Tons.
Bessemer.....	1,859,259	28.5	1,478,639
Open-hearth.....	4,663,489	71.5	3,817,103
Total.....	6,522,748	100.0	5,295,642

The division, according to acid and basic steel was as follows in 1908:

	Acid.	Basic.	Total.
Bessemer.....	906,466	673,073	1,478,639
Open-hearth.....	2,578,940	1,238,263	3,817,103
Total.....	3,485,306	1,810,336	5,295,642
Total, 1907.....	4,663,095	1,867,653	6,522,748

The increased proportion of basic steel last year was due to the fact that the decrease in basic open-hearth production was very much smaller than in any other kind.

The production of finished material of all forms from open-hearth ingots is re-

Behavior of Tellurium in Assaying

Previous writers have been in substantial agreement regarding the use of a basic slag in crucible assays of telluride ores and the conducting of the fusion slowly at moderate temperatures. The behavior of tellurium in assaying has been investigated by S. W. Smith (*Inst. Min. and Met.*, Bull. 44).

The effect of litharge on tellurium was investigated in various ways. Lead buttons containing lead, 6 parts; gold, 1 part tellurium 1.5 parts; were fused or soaked under litharge at a temperature of about 800 deg. C. for 15 min. and then cupelled. The litharge was black, lustrous and opaque. The lead button when cupelled yielded 96 per cent. of the gold. Duplicates of these fusions were left in the furnace and the temperature raised to 1000 to 1100 deg. C. for another 15 min. and on cupelling the recovery was only 94 per cent. The slag was dark, red and glassy; evidently some of the tellurium had been reduced as indicated by the gold recovery. Again, equal portions of pure lead were fused separately with samples of the opaque and the glassy

slags containing equal quantities of tellurium, with the result that the lead from the fusion with the opaque slag showed far more tellurium than the other. This would seem to indicate that a portion of the oxidized tellurium is reduced again when the temperature is raised.

A lead button of the same composition as previously described was dropped into litharge to which a little sand had been added, and which had been kept at a temperature of 1000 to 1100 deg. C. for 30 min. and allowed to remain in the furnace for 10 or 15 min. more. The weight of the button was unchanged and it was completely absorbed on cupellation. The slag was straw color and gave no indications of tellurium except for a slight reddish cloud, near the button. A repetition of the experiment, except that after the formation of the silicates the temperature was lowered and maintained at a low point after the introduction of the button, gave similar results. After the formation of silicates there is practically very little tendency for the tellurium to oxidize. An examination of the slags seemed to indicate that the reaction between the litharge and tellurium is represented by the equation:

and that the reverse of this reaction takes place at higher temperatures.

The effect of scorification, unless the operation is carried out at a moderately low temperature, is to concentrate the tellurium in the button. The most effective way to remove tellurium is to "soak" the button under litharge either in a scorifier or crucible at low temperature.

The effect of tellurium in a lead button containing gold and silver is to weaken the surface tension of the molten metal during cupellation. This effect of tellurium, assisting the general tendency of the film of litharge in the same direction, results in the tendency of the molten metal to "wet" the sides of the cupel. If the amount of lead is small in proportion to the silver, gold and tellurium, small portions of metal become detached and either pass into the cupel or leave minute beads.

Lead is more readily oxidizable than tellurium, especially at high temperatures; if sufficient tellurium remains toward the end of the cupellation, complete absorption may take place, or in other words, complete absorption and subdivision are the result of insufficient lead. The tendency to become "wetted" is greater with bone-ash cupels than with patent cupels.

The presence of silver protects gold by acting as a diluent during the cupellation of buttons containing tellurium. The absorption loss due to the presence of tellurium is a function of the temperature of cupellation. An excellent bibliography is given in connection with the paper.

The Panel System as Applied to Metal Mining

The Conditions to Be Met Were a Wide Orebody with Horizontal and Vertical Jointings, and a Weak and Treacherous Hanging-wall

B Y H. E. W E S T*

In metalliferous mining the efficiency and economy of extraction is largely governed by the physical characteristics of the deposit. Usually ore deposits are bounded by recognizable walls, although one, and possibly both, may be lacking in definition. Perhaps of all factors that determine the method of extraction, the character of the walls and the width of the deposit are preëminently the most important. The nature of the walls, especially that of the hanging, is an essential consideration. The character of the employees has to be considered, especially when dealing with unskilled native races.

grades toward the footwall.

The hanging-wall is composed of a crushed slicken-sided shale, possessing no element of stability; indeed, when at all laden with water, it behaves much like sand or thickened mud. In this shale occur ill-defined stringers, that are, however, very rich. The ore is usually from medium to hard, varying from a silica gangue on the hanging side to a barite gangue toward the footwall. The ore is stoped to a width of about 50 ft. The deposit is contiguous to the contact of an igneous and sedimentary rock, the ore being a replacement of the latter. The dip

very considerable water circulation exists along the slate hanging and, during spring, within the orebody. The one markedly favorable feature is the firm footwall and ore toward that wall.

FIRST METHOD OF WORKING

The initial method of opening up this deposit was by a center drive, cribbing and filling with waste rock. On working toward and approaching the hanging-wall, the inclined jointing or bedding planes caused the ore to break higher than the normal stope and thus expose an undue surface of the weak hanging. The conse-

FIG. 1. TYPICAL ORE SHOOT

Much depends on the character of the orebody, whether it is hard or soft, homogeneous or broken with slips or faults, or even blocky, with well developed joints or bedding planes.

As an example of the evolution of a system suitable under certain conditions, a deposit such as is illustrated in the accompanying sketches may be considered. Fig. 1 shows the shape of the deposit, together with the segregation of the several grades of ore. It will be seen that roughly the orebody may be divided into three classes: (a) Low-grade; (b) medium-grade ore; (c) rich ore. The richest ore lies against the hanging-wall, the lower

is about 70 deg. southerly. The particularly unfavorable feature of the orebody lies in the almost horizontal joints, that probably represent the bedding planes, together with a vertical jointing connecting same. The "horizontal" joints are actually inclined upward toward the slate hanging. The footwall is a hard clastic rock, considerably softened by water flowage along the line of contact.

The conditions here presented are a wide deposit, with an extremely weak and treacherous hanging-wall; the roof of the orebody has seams and joints and, moreover, is considerably faulted after deposition. The eastern end is more shattered and is probably weaker than the western. A

quence was that the wall ran and the roof settled, often in large masses. The hanging-wall streak was temporarily left to support the weak wall. It was found a matter of considerable difficulty to extract such ore afterward; in fact, much of it never was recovered.

On the sill stope being taken out, cribbed and filled, and on the second stope being opened up for stoping similarly, still greater falls were encountered. The settling of the hanging, moreover, was so severe that the cribs and level sets were thrown over and the latter fractured so that eventually the level had to be abandoned.

A little reflection showed the unfavorable and also certain favorable and char-

*Mining engineer, El Oro, Mexico.

acteristic features of the deposit, which evidently had to be taken into account in evolving an efficient method of extraction. It was evident that stoping toward the hanging-wall encountered peculiar difficulties. It was also evident that but little of the hanging could be exposed, unsupported with timber, at one time. It was equally clear that were any considerable area of roof left without support, a serious fall might be expected, which had the particular disadvantage of spreading upward and proving troublesome in each succeeding stope. To maintain a center drive open by any system of timbering was impracticable. Masonry was inadvisable, and probably would have shared a similar fate. Moreover, a central drive was unnecessary, unhandy for tramping, and unfavorable for the maintenance of chutes.

THE PANEL SYSTEM

Clearly the first thing to do was to open

of the panel (about 20 ft.), unless under a firm roof, when the whole width could be safely stoped. The second slice was then filled, and the third extracted and filled, and so on toward the footwall. Thus was the half panel extracted from the hanging to the footwall. Greater freedom was exercised toward the footwall, owing to the firm character of the roof; still, this liberty could not be abused. Alternate half panels were thus extracted and filled. With the roof packed with filling, together with what sets or cribs were essential, there was little trouble experienced in extracting the remaining half panel in a similar manner. When conditions would permit, such as in the western end, panels could be turned off the lateral and stoped for the full width toward and up to the hanging. In such cases both roof and hanging were firm. Modifications between the two methods were utilized, governed by conditions.

the chute being protected with a grizzly made of 2 $\frac{1}{2}$ -in. angle iron set 6 in. apart; these were firmly spiked to the chute timbers. Winzes were sunk at 50-ft. intervals from the level above and near the footwall for chuting down filling within each panel.

OPENING UP THE LOWER HORIZON

Figs. 2 and 3 show how it was proposed to open up a lower horizon, where speed was an important factor. A preliminary, though optional, lateral is here shown in the hanging. From this crosscuts are periodically turned off. These crosscuts serve to show definitely any ore in the slate and also the extent of ore on the footwall, and determine where the footwall lateral may most advantageously be run by connecting such crosscuts. This slate lateral is then filled, as it has served the purpose. The slate, with what ore it may contain, is then extracted against the

FIG. 2. PROPOSED METHOD OF OPENING UP LEVEL WHERE SPEED WAS A FACTOR

up a rock drift along the contact, where the ground was favorable, and, moreover, rendered sufficient support to maintain such drift permanently. From the rock-drift crosscuts were driven through the deposit at 50-ft. intervals, until the hanging wall was reached. The orebody was thus cut up into panels of about 45 ft. in width. The next operation was to connect the several crosscuts by running a small drift in the slate, taking out what stringers might be encountered, timbering this drift with light sets, and filling with, preferably, large rock. Thus a solid bulk head was erected against the soft hanging to the full height of the stope, maintained at 7 ft., and throughout the length of the shoot. The second slice of about 6 ft. wide, consisting mainly of the rich streak, was extracted, but only through one half

Every stope was carefully carried to 7 ft. in height, and worked out squarely against the hanging- and footwall. Two horizons could be simultaneously worked and, indeed, such was advisable, so that the production should be continuous and not suffer through all the preparatory blocking out falling at one period. Usually the ends were maintained in advance of the middle of the stope. Subsequent stopes were opened out and worked in a similar manner, cutting down both lateral and crosscut over the ones below, but leaving the roof of the rock drift intact. Cribbed bins were placed at the mouth of each crosscut and midway between, or about 25 ft. centers. The bins were 3 ft. square within timbers, each alternate chute being provided with a manway. All chutes delivered into the lateral, the mouth of

hanging wall streak as before, timbered and filled. Stoping then proceeds as shown.

Doubtless much of this preliminary work seems superfluous. It is capable of some modification, as for instance, the preliminary drift may be omitted and the footwall lateral run from the main crosscut and the work expedited from the several winzes sunk. The footwall rock being much harder, considerable more time would be consumed whilst, in this case, was an element of importance. Again, where the hanging wall was firm and the roof favorable, the panels could be driven from the lateral and breast stoped toward the hanging.

It was impracticable to carry forward a wide breast longitudinally as in a solid orebody, or lodes with firm walls. Square

setting, though an admirable method, was impracticable both by reason of a limited timber supply and inefficient labor. Of course, had the shaft been on the footwall, there would have been no need to maintain a tramming road through the deposit.

FEATURES OF THE SYSTEM

The essential features of the method, which I call the "panel system," are as follows: (1) The footwall lateral, giving easy access to the deposit and insuring the permanence of the tram road. (2) The cutting up into panels, with waste-filling and ore-discharging facilities in each. (3) The extraction first either of the slate on the hanging, against the rich streak, or the rich streak itself, with the formation of a solid rock-filled bulkhead.

prevented by this panel method and, moreover, a high extraction is secured throughout the deposit.

In addition, the roof is so well secured that any considerable fall is improbable. Consequently, the stopes go up in solid ground, without the inconvenience and expense of 'spiling' or supporting ground that has been allowed to break away overhead. A clean extraction and the keeping of the ground in place is assured. It is imperative to start the sill stope right. To maintain the roof intact at the first stage is to maintain it intact throughout, with the converse equally true.

The timber consumption is moderate, usually confined to small timber, much of which is available for reuse. The ventilation is always good. Filling is supplied with little handling where required, and

A Successful Rhodesian Gold Mine

SPECIAL CORRESPONDENCE

The report just issued by the Globe & Phoenix Gold mine of Rhodesia states that during the year 1908 the ore milled was 75,413 tons at a cost of \$6.24 per ton including 96c. for development redemption. Working costs have been reduced 48c. per ton compared with the previous year. The value of the bullion won amounted to £154,555, or \$9.84 per ton. After deducting administration charges in London and depreciation the profit for the year amounted to £39,511. Four dividends of

FIG. 3. METHOD OF STOPING WEAK ROOF AND HEAVY HANGING-WALL: "PANEL SYSTEM," SECTION STOPING AND FILLING.

(4) The exposure of a small area on the roof, by sectional stoping; and the stoping of half the panel leaving pillars; the supporting of the roof by filling, and subsequently the safe stoping of such pillars. (5) The comparatively large area of stoping ground exposed; the safety of the workmen, as they are never far from a safe lateral or crossover. (6) The determination of the definition of the deposit, insuring no irregular stringers or branches being overlooked on the hanging and on the footwall, the complete blocking out of all low-grade ore. (7) The manifest facilities for estimating the grade and quantity of the ore, and the maintenance of systematic assay sheets for each stope.

It will be seen that as the hanging-wall streak is of great value, any admixture with fallen slate would occasion considerable loss; especially so as such ore is scarcely distinguished from slate. This is

the ore, with a short shoveling, or wheel, is fed into the chutes, which are readily accessible and at frequent intervals.

On the other hand, there is considerable blocking out to be done, which means expense. This is largely compensated for by the number of working faces open, an especially desirable feature, as often toward the hanging-wall the ore won daily from any particular working face is small.

It may be of interest to add that the panel system is a development of the "pachua" or "lateral-drive" method used in Mexico for wide lodes with soft or hanging wall, adapted to the peculiar conditions caused by a combination of weak hanging and fallen ground at the Yuspensky mine, Siberia. The method was subjected to many modifications dependent on the nature of the ground. The opening out and stoping by panel was, however, maintained.

24c. each per share were paid making a total distribution for the year of 20 per cent on the issued capital of £200,000.

The development of the mine was satisfactory and the ore reserves were increased from 100,155 tons of a value of 11.1 dwt. at the close of 1907 to 1,43,348 tons of a value of 10 dwt. at the close of 1908. This increase in value and tonnage is due to an improvement in the mine at the 14th and 15th levels.

The main shaft is down 2307 ft. making it probably the deepest mine in Rhodesia. The poor extraction obtained in the mill, referred to by the consulting engineer is due to the presence of antimony. A sorting and jigging plant has been erected, but as the new plant did not start until late in November, no reliable data are yet available as the benefit to be derived therefrom.

An Improved Type of Mine Car Wheel

By J. E. JOHNSON, JR.*

One of the principal difficulties in mining operations is to obtain cars so constructed that they will turn around the short curves required without undue friction and at the same time will have wheels and axles that are reasonably durable. The difficulty arises from two circumstances, one of which is that where the wheel base of the car is an appreciable fraction of the radius of the curve, the axles are not coincident with the radial lines of the curve. This makes the flanges bite and runs the rolling friction up very high. The only cure for this trouble is to place the wheels as close together as the radius to be turned may require. But it must be borne in mind always that the stability of the cars lengthwise will be small if the two wheels are close together; and if the car bodies are long the strain on them, being supported only at the center, will be high.

THE GREATEST DIFFICULTY

The more important difficulty comes from the fact that the outside wheel on a curve has to travel through so much greater distance than the inner, when the radius is short, that the effect in going around the curve with both wheels fast to the axle is as much like a sled as it is like a wheeled vehicle. Just what this can amount to is not generally appreciated. A right angle turn of 20 ft. radius and a gage of only 3 ft. will cause the outside wheel to go 15 per cent. farther than the inside one. So with tight wheel cars there must be a relative skidding of $7\frac{1}{2}$ per cent. of the distance traveled on each wheel; that is, one wheel must skid backward 2.4 ft. and the other forward an equal amount, or in some way there must occur skidding to the amount of 4.8 ft. What this means in pulling a heavily loaded car around a curve is obvious.

The effects of this have been so objectionable that most mine operators have gone to the other extreme and use cars with both wheels loose on the axle, the axle itself not turning. These are now always made with self-oiling hubs and the cost of lubricating such wheels is much less than it formerly was; but wheels of this type are open to an objection inherent in their construction. The wear necessarily makes the hole through the hub constantly larger and the axle constantly smaller. The result is that wheels soon become "drunken" and get so much play that they split frogs, drop through any possible place in the track that is at all wide of gage, and become so utterly objectionable that they have to be replaced with new ones.

The same condition of drunkenness

does not obtain with the tight wheel cars for the reason that the two wheels and the axle in the latter case constitute practically a single structure of so much larger size than the single wheel that an equal amount of play would correspond to much less wear. But far more important than this is the fact that the wear is in only one direction, viz.; upward into the journal boxes, and this wear is always taken up by the weight of the car with the result that a pair of wheels may be worn until the rails have cut through their treads without showing any signs of drunkenness. These facts are quite generally known and understood but this review of them has been given in order to pave the way for what is to follow.

SOLUTION OF THE DIFFICULTY

The solution of the entire difficulty is absolutely simple and inexpensive. The particular one which I have in mind may or may not be known to the mining public, but considerable missionary work on some of the best wheel manufacturers has been necessary to induce them to make

side and in two pieces with a cellar if the journal is inside the wheel. The superiority of this construction over the loose wheel construction is so great in practice that it will not be believed by most people until they have made a trial of it; but there is a good reason for this superiority.

All mine tracks are more or less curved but the average radius of curvature is generally not very small. In coal mines, for instance, there are right-angle bends turning off from the main entry but there are hundreds of feet of straight track leading up to these bends and leading into the room beyond them, so that in coal-mining practice probably 80 per cent. of the track is perfectly straight, and if the curvature of the remainder is 20 ft. centers this would make the average radius of curvature 100 ft. This is rather an extreme case but deliberately so taken. If now the gage be 4 ft. one wheel will have to travel 4 per cent. faster than the other on this average radius. With the type of construction described the tight wheel drives the axle positively.

The Engineering & Mining Journal, N.Y.

CONSTRUCTION OF CRANK IMPACT DRILL

the wheels which avoid the difficulty. It would seem, therefore, that publication again may not be amiss even though the ideas set forth are old to some.

The solution of the difficulty is to make one wheel on each axle tight and one loose and let the axle run in journal boxes. The simplicity of these in construction will astonish those who have never tried it. Journal boxes of the commonest type may be employed and whether they are outside the wheels or inside makes no difference. One wheel is pressed on to its axle just exactly as in ordinary railroad practice. The other wheel may or may not be of the self-oiling type but it is made a running fit on the axle and if not self-oiling, grease cups are provided for lubrication. Any desired arrangement of collar or groove to hold the wheel in its proper relation to the axle may be used. One of the standard modern construction of self-oiling wheel with a key in a groove in the end near the axle inside the hub is about as good as any. The axle should preferably be held to its place by the tight wheel and one collar or by two collars between the journal boxes. The journal boxes are made in one piece if the journals are out-

The other wheel in the case assumed would turn relatively to the axle 4 per cent. of its total revolutions. In other words, the relative wear between hub and axle would be exactly one-twenty-fifth of what it would be with two loose wheels. This amount of movement is so small that with a properly constructed hub no objectionable degree of wear will be developed until the tread of the wheel is worn out.

INTERESTING POINTS REGARDING TRUCKS

I have bought standard trucks, that is wheels, axles and axle holders, from one of the best manufacturers in the country. These trucks were of the loose-wheel type. The hubs were extra long, an excellent self-oiling arrangement was provided, and everything was done to prevent wear and the consequent drunkenness; but after a short time these wheels began to get loose on their axles and the cars gave trouble by getting off the track. As the cars with their load weighed about three tons, sat very low to the ground, and had a very short wheel base, this was most objectionable. These wheels had been bought on the reputation and guarantee of the manufacturer, rather

*1002 King street, Wilmington, Del.

contrary to my own judgment of what was right, but it did look as though the people who made wheels ought to know more about them than the man whose misfortune it was to have them to use, so we bought about 30 or 40 sets of this kind in groups of ten. By the time the last group was put into use it became evident that the inevitable consequences of the loose-wheel construction existed in this maker's design as well as poorer ones, and in spite of conscientious efforts to remedy it. Thereupon inquiries were made among mine-car manufacturers for trucks of the tight-and-loose-wheel type. One manufacturer agreed to make them at a price about the same as that required for the two loose-wheel construction, the boxes, cellars and babbitt being included in the quotation.

These wheels were put in service, with results that were, from a practical point of view, almost disastrous, because the people who had to use them showed such a great preference to them that they were almost unwilling to continue to use the loose-wheel type. These wheels have now been in use for a period far longer than it took to develop drunkenness in the loose-wheel type, without showing a sign of this or any other defect. They are oiled by waste in the cellar, as in standard railroad practice, with great economy of oil. The loose wheel of course requires to be oiled occasionally but on account of the very small amount of rotation required this is a factor that is almost negligible.

Cost

As to cost, it must be noted that this construction permits the use of one wheel with plain hub instead of the more expensive self-oiling hub. The boxes for fastening to the mine-car frame are but little more expensive than the cast-iron holding-blocks furnished for this purpose by the manufacturer aforesaid for the loose-wheel type of truck. The net result is that the first cost per set is not much different in the two cases. The advantages of the tight-and-loose wheel construction are: (1) Far greater durability; (2) Much greater rigidity as a construction approximating to the standard tight-wheel type of construction; (3) In consequence of the two preceding advantages infinitely less trouble with derailments and consequent injury to tracks, cars and wheels; (4) A reduced consumption of oil; (5) As a result of the greater durability with virtually the same cost, lower annual cost for wheels.

There is no intention on my part to patent this construction. In fact, the probabilities are that it is very old in the patent office, but its merits are very high and should be more widely known. I have no hesitation in saying that its universal adoption in the mines of this country would result in a saving of

hundreds of thousands of dollars per year.

A Novel Rock Drill

By A. GRADENWITZ*

The crank impact-drill represented in the accompanying illustrations has been designed recently by the Siemens-Schuckert works. It is operated by a 1-h.p. motor, fitted directly to the drill and is said to be far more efficient than the usual design of rock drill with flexible shaft and motor box. The electro-motor is located in a saddle in the back of the drill and is rapidly removable.

DRILL ON RIGHT OF COLUMN; MOTOR ABOVE DRILL

Like the drill itself, it is inclosed in a dust- and water-proof casing. According as the drill is working on the right or left side of the supporting column, the motor is placed above or below the drill. This difference in the location of the motor, however, exerts no influence on the working of the drill; it may be used as well on a horizontal column or transportable supports provided it is fitted with a special feeding slide. If employed with a convenient fitting, the drill can be used as well for cutting and cleaving.

This electric drill can be used in boring rocks of any hardness. The initial diameters of bore generally vary between 40 and 50 mm., the adoption of a

smaller diameter being advisable only in the case of very substantial rock. A length of 5 to 10 cm. per minute can be drilled in hard granite with 35 to 40 mm. diameter of bore, and 15 to 30 cm. in sandstone, according to the hardness of the latter. For drilling soft rock or earth, a rotary drill of lighter and cheaper construction should be used.

A special advantage of the crank drill illustrated is its low consumption of energy, six drills being operated at a time with an expenditure of 10 h.p. The amount of electrical energy consumed by each machine is 1 k.w. and no energy is used up during the exchanging or shifting of the drill, the motor being then stopped.

Current is supplied through flexible well-insulated conductors wound upon transportable drums in lengths of 60 to 100 m. These cable drums are located permanently near the connection box, which contains the terminals of the sta-

DRILL ON TRIPOD FOR QUARRY WORK

tionary circuit and fuses for each pole, the length of the conductor actually used being wound off the drum. At the loose end is attached a substantial plug, designed for rough handling, which fits into a contact box of the motor. After fitting this plug, the operator has only to turn the crank situated on the motor to start the latter as well as the drill.

The motor drives through a spur wheel gearing a double-bearing crank shaft provided with a flywheel, which in turn effects the alternate motion of a slide. In the latter are incased the two working springs surrounding the impact piston, keeping between them the flanged impact box, which is susceptible of a rotation, but not of a longitudinal motion on the piston. The reversal of the drill after

*Berlin W 56, Regensburgerstrasse 3.

each stroke is effected in the well-known manner by means of a nut with one-sided click which engages with the elongated thread of the impact piston. The click-holder of the ratchet nut is located on springs, so as to prevent any damage to the nut. Two men are required to operate the machine. The weight of the latter, exclusive of the motor, is 100 kg., the removable motor being 47 kg. and the supporting column (of 125 mm. diameter) 115 kg. in weight.

The Chile Mill

By M. R. LAMB*

The article by Captain Narvaéz which appeared in the JOURNAL of Nov. 21, 1908,

in that the Pachuca mills are set in wooden frames, while the El Bote mills have steel framework.

The comparison between the two styles of mill, Chile vs. stamps and tube mills, is shown in the accompanying table. Capacity is based on ordinary quartz such as is produced by the mines of Pachuca. The San Francisco, San Rafael and Progreso stamp mills are treating ore from the same mine that supplies Captain Narvaéz' mill, and this ore is considered to be of average hardness. The ore at El Bote is quite hard and dense, yet the Chile mills crush 18.6 tons per 24 hours through 180 mesh, of which 70 per cent. passes 200 mesh.

The figures given in the table are based on cost of ironwork without framing, as the latter would be about the same in either case. The tubes figured were 3.5x14

room, the loss of which is much less with the Chile mill, thus giving greater latitude in choice of sites. Less actual ground space is also required. Supporting framework, building and erection costs, including a simple hand crane for the Chile mills are about the same in either case, while depreciation, attendance (skilled as well as unskilled), accessory equipment, breakages and probable delays are all decidedly in favor of the Chile mill. The best quality of the stamp mill, its ability to withstand rough handling, is possessed by the Chile mill. Neither over-feeding nor under-feeding has any effect on its continuous operation, these conditions merely reducing capacity temporarily. The accompanying cuts show six such Chile mills as erected in the shops preliminary to shipment to Mexico.

CHILE MILLS ERRECTED IN SHOPS READY FOR SHIPMENT

describing his milling plant, and giving general information concerning his Chile mills, deserves careful study. He makes claims for his mills which are really startling when compared with a combination of stamps and tube mills.

Before analyzing his results it will be of interest to state that approximately similar results are attained by Mr. Pattinson at the El Bote mine in Zacatecas, Mexico, where the same Allis Chalmers Chile mills are in use. The only difference between the two sets is in the number of mills and

ft., and the stamps 1050 lb. Among the points not covered in the table is head

According to Consul-General Julius G. Lay, of Cape Town, it is believed that the most promising petroleum field yet discovered in Cape Colony is situated at Zwart Kops, near Port Elizabeth, where one well has already been sunk about 2000 ft. In the district of Carnarvon, there are surface indications of petroleum and a well is being sunk.

Statistics collected for THE MINERAL INDUSTRY show that in 1908 the production of crushed steel in the United States was 630,000 lb. (\$44,100), against 840,000 lb. (\$58,800) in 1907.

Selection and Use of Bits for Power Drills

A Discussion of the Different Types of Drill Bits, Bringing out the Effect of Size, Shape and Cutting Edge on the Results Obtained

B Y M . D E G E N N E S

The success of almost every drilling operation depends on the selection and treatment of the bits. If the steel has been carefully selected and the bits properly formed, sharpened and tempered for the work, and if they are changed just as soon as their gages and edges are worn, the results will be economical. The functions of the drill sharpener should be considered as of almost equal importance to those of the chief mechanic in charge of the drills. The best sharpener is not any too good, even if he does not have enough work to keep him busy all the time. It is cheaper to let a high-salaried drill sharpener and his assistant loaf part of the time, than to have two or three drill gangs changing bits every few minutes, or pounding on the drill stem to start the bit when it is stuck, thereby only ruining the inside mechanism of the machine.

SHAPE OF THE DRILL BIT

The flat bit is the oldest form. When it has a straight cutting edge (Fig. 7), the shock is very severe on the drill; when the edge is pointed (Fig. 6), the shock is less severe, but in both cases, and especially with the straight cutting edge, the bit has great difficulty in turning, and in cutting the outer edge of the hole. Such a bit generally turns in jerks, and makes a three-cornered hole.

With air not highly compressed as was the case in former days, a pointed, flat bit would move so slowly that it would have time to turn in the hole, but even then it was severe on the turning mechanism. As pressures increased, the speed of the bit increased but its turning ability remained the same, resulting in universally three-cornered holes. When a cartridge is put into this kind of a hole, there is always an air space in the corners that detracts from the power of the explosion. • Star or mitered bits were then tried, and if they did not come into immediate favor it was because they were so hard to make, even for the most experienced blacksmith. Within recent years specially shaped swages have come into use, and star bits are now easy to make.

The cross bit, which is the form most commonly used, can be made in several shapes. The corners may be behind or in

advance of the center; the cutting edges concave or convex, with straight or curved edges; the upset part of the bit may be long or short, thin or stubby; and the angle of the cutting edge may be sharp or obtuse. Let us examine the effect on the rock of each of these forms of bit.

The bit shown in Fig. 8, which is the most commonly used, has a concave cutting edge; after using such a bit, the central part is found to be much less worn than the outer, probably because the blows of the corners weaken the rock at the center of the hole, leaving less work for this part of the bit. With the convex bit shown in Fig. 9, on the contrary, the

marble, sandstone and other soft, homogeneous rocks.

The X-bit (Fig. 5) is most useful in thinly bedded rock, for drilling holes parallel to the bedding. A cross bit, in these circumstances, is likely to fitcher and give difficulty in turning. The X-bit overcomes this objection.

SHAPE OF THE CUTTING EDGE

Figs. 1 and 2 show two bits designed for homogeneous hard rocks. They are identical except for the angle of the cutting edge; that in Fig. 1 has about the sharpest angle that it is possible to use without danger of breaking the steel. That in Fig. 2 is one that can be used

rock is solid clear to the center of the hole, the corners have less work to do and the center of the bit therefore gets most of the wear.

With the pointed cross bit (Fig. 10) all the work is done by the center, since the corners come into contact only with the fissured part of the rock. The rock around the edge of the hole breaks suddenly leaving the point of the bit striking alone for a few blows; by the time the full face of the bit has begun to work again, another lateral fissure has formed in the rock, which breaks off suddenly and the operation is repeated. The only advantage of this type of bit is seen in quarries, where holes are put down in line. The shape of this bit permits a hole to be placed exactly where it is wanted but it works well only in

in rocks of varying characters, without change. While working in hard rock, the sharp-angled edges can be used, at full pressure, without danger of blocking the mouth of the hole, since the quantity of rock broken off at each blow is so small that the mud is readily drawn out with the return stroke, especially as this is the more vigorous when working at high pressure. If use is made of this kind of a bit, under full pressure, in a soft rock, the cuttings would be of so much greater volume that they would not be discharged freely, especially as the rebound of the drill in a soft rock is less vigorous. The remedy is either to decrease the speed of the drill, which is not desirable, and only reduces its ability to withdraw the mud, or to use a more obtuse cutting edge (Fig. 4). Sometimes

NOTE.—Abstract of a paper presented at a meeting of the Société de l'Industrie Minérale at Paris, Nov. 26, 1908.

the edge must be so obtuse as to be almost flat, to give good results.

LENGTH OF UPSETTING

The length of the cutting blades, the upset part of the bit, should vary with the nature of the work to be performed. Figs. 1 and 2 show the maximum length for use in a very hard rock; Figs. 3 and 4 show shorter bits, in which the cuttings have a freer opportunity to escape, making this the most desirable form for usual work. A short upset also gives faster clearance of the cuttings. In a rock, however, which grinds the sides of the bit, reducing its dimension rapidly, a long upset should be given.

The wings, or blades, of bits having the dimensions shown in Figs. 1 to 4 should be not less than 16 mm. thick. They must be of the same thickness throughout, to permit rapid removal of the cuttings. If the gage is to be less than 57

delays the drilling, wastes power, and adds to repairs.

For example, suppose a workman is given two sets of freshly sharpened steel to bore a certain distance in a moderately soft rock in which, let us say, each set will bore two holes without difficulty. In the third hole, the drills will stick and the workman will pound on the stem with a hammer or wrench, and rather than go to the surface, find the blacksmith and get a fresh set of drills, will waste more time in trying to drive the third hole than he took for the first two. I have known mine managers who have laid heavy penalties on every drill runner whose bits show marks of having been pounded.

As soon as the gage of a bit has been so reduced that its hole fails to take the next following bit, of smaller size, it is better to take a new set altogether. Even if one bit of the set appears to be still

Foreign Trade in Iron and Steel

Iron and Steel Exports—Exports of iron and steel, including machinery, from the United States for the four months ended April 30 are valued by the Bureau of Statistics of the Department of Commerce and Labor at \$58,155,091 in 1908, and \$48,209,062 in 1909; a decrease of \$9,946,029, or 17.1 per cent. The leading items of export were, in long tons:

	1908.	1909.	Change.
Pig Iron.....	11,915	10,560	D. 355
Billets, ingots & blooms	34,269	36,264	D. 14,005
Bars.....	19,125	21,494	I. 2,369

There were several increases in quantities during the month of April.

Iron and Steel Imports—Imports of iron and steel and of machinery into the United States four months ended April

mm., the blades may be proportionally shortened.

GAGE

In order to maintain a hole to size, it is very important that the cutting edges be straight and not curved, as in Fig. 8. The wear on the corners of such a bit would prevent the maintaining of the proper bore. The amount of work that a bit will do before losing its dimension should be accurately ascertained. In the hardest rocks it is never possible to use a bit the second time, and the greatest length that can be drilled is the total length of the feed, or 60 to 75 cm. in the largest machines. It is necessary, therefore, to have a sufficient supply of bits on hand so that a new set can be used for each hole. In a soft rock, or in an ore, it often happens that the cutting edge is not dulled, even after having made several holes; the runner is then likely to neglect the question of gage, as long as the cutting edge is sharp, and gets into difficulty, for it is the diminution in the size of the hole that causes friction,

good, time will be saved by taking an entirely new set. In a moderately soft rock, in which a bit will satisfactorily drill more than one hole, the engineer should determine by experience just how many holes may be drilled by each set, and the blacksmith and the drill runner need not be consulted in this matter. The runner should be instructed to drill only so many holes with one set as the engineer prescribes, and the blacksmith should be required to furnish bits to exact gage. This plan necessitates a large number of bits, but the advantages in more rapid work and fewer repairs more than outweigh this expense.

Statistics collected for THE MINERAL INDUSTRY show that in 1908 the amount of magnesite produced in the United States was 8,967 short tons, valued at \$52,342. This is larger by 2502 tons than the 1907 production, but the value of the output is lower by \$5378. California contributed practically all of the production of the United States.

30 were valued at \$7,113,203 in 1908, and \$7,941,493 in 1909; an increase of \$828,290, or 11.6 per cent. Leading items of imports were, in long tons:

	1908.	1909.	Changes.
Pig Iron.....	32,192	40,292	I. 8,100
Scrap.....	1,621	1,558	D. 63
Ingots, blooms, etc.....	3,069	4,261	I. 1,302
Bars.....	10,788	8,827	D. 4,961
Wire-rods.....	4,008	4,157	I. 152
Thinplates.....	21,699	17,686	D. 4,013
Sheets and plates.....	895	1,494	I. 599

The only considerable change was the decrease in tinplates.

Iron Ore Movement—Imports and exports of iron ore in the United States, four months ended April 30, long tons:

	1908.	1909.	Changes.
Imports.....	238,589	350,440	I. 111,851
Exports.....	29,646	32,921	I. 3,255

Of the imports this year, 230,082 tons were from Cuba.

Imports of manganese ore four months ended April 30 were 73,626 tons in 1908, and 68,123 in 1909; decrease, 5503 tons.

The Chinese imperial agent at Lhasa has been instructed to prepare a full report on the gold deposits of Tibet.

Operations of Utah Copper Co. During 1908

More Than 10 Miles of Tunnels, Drifts and Raises Driven; Proportion of Ore Removed by Stripping Shows Increase; Output 56,895,998 Pounds

B Y D. C. J A C K L I N G *

In the last annual report it was stated that the underground developments, on Dec. 31, 1907, amounted to approximately 90,000 linear feet of workings. Since that time, we have driven more than 10 miles of tunnels, drifts and raises; but, at the same time, we have destroyed a very large percentage of our underground workings, partially by stoping operations in connection with our underground mining, but more largely as the result of the opera-

result of the destruction of both old and new workings in the manner above described, we have not now to exceed approximately 20 miles of openings available for use in underground methods of mining, or accessible for inspection.

In the report for the year ending June 30, 1907, the statement was made that the developed and partially developed area amounted to 72 acres. Developments since then have resulted in extending this

have made during the period has been that fully developed ore remains approximately as stated in our last annual report, viz., 20,000,000 tons, as the area of this class of ore has been increased to an extent that will more than offset the quantity of ore mined.

The two classes of partially developed ore, described in the former report, have been increased in the aggregate to the extent of approximately 8,000,000 tons, as

PARTIAL MAP OF SALT LAKE COUNTY, SHOWING RELATIVE POSITIONS OF UTAH COPPER COMPANY'S MINES, MILLS AND RAILWAY CONNECTIONS

tions of steam shovels over areas that had been previously blocked out by tunneling and drifting. The areas containing these workings have, to a certain extent, been dug out by steam shovels but have to a greater extent been excavated by heavy blasting incident to steam-shovel work, so that they are not now accessible. As a

area about 8 acres, so that now the known ore area, fully and partially developed, is approximately 80 acres. The ore thicknesses and values of this additional territory are, generally speaking, similar to those described in the former report, so that the new developments have resulted in additional ore reserves to the extent of about 8,000,000 tons, or at a rate during the period of over three times the rate at which ores were extracted for reduction. The net result of the developments we

above stated, so that we now estimate 60,000,000 tons in these two classes of reserves. In other words, of fully developed, partially developed and reasonably assured ore, the total amounts to about 80,000,000 tons. Of this total tonnage, 65,000,000 tons can be classed as of the better or normal grade, averaging about 2 per cent. copper, and 15,000,000 tons as of the lower grade, approximating 1½ per cent. copper. In addition to this, we have the lower zone, as described in the previous annual

*General manager, Utah Copper Company, Salt Lake City, Utah.

NOTE—Taken from the fourth annual report of the Utah Copper Company, for the 18 months ending Dec. 31, 1909.

report, the average value of which has been indicated to only a limited extent by diamond drilling, but which is estimated to contain a minimum of 40,000,000 tons that will probably average $1\frac{1}{2}$ per cent. In discussing the above quantities throughout, consideration should be given to the fact that the stated figures include the quantities of ore mined during the fiscal period. This would amount, in percentage, to approximately 3 per cent. of the above described three classes of ore aggregating 80,000,000 tons reserves.

All the development done during the period has been on the easterly end of the property and on both sides of the cañon, but the larger part of it has been on the south side of the cañon, in the southeasterly portion of the company's territory. The ore-bearing area is still being extended in that direction.

STRIPPING

Stripping operations since their commencement, in August, 1906, have resulted in the removal of 1,705,322 cu.yd. of capping. Of this amount, 1,335,233 yd. were removed during the fiscal period under discussion. During the first six months of the fiscal period, 367,950 cu.yd. were removed; during the second six months, 446,460 cu.yd. were removed, and during the last six months of 1908, 520,823 cu.yd. were removed.

The total area over which stripping operations have been conducted to date is 19.7 acres. The average thickness of capping, as disclosed by these operations, remains the same as that stated in our last annual report, approximately 70 ft. corresponding to 113,000 cu.yd. per acre. The total amount removed is, therefore, equivalent to stripping of, approximately, 15 acres and, at the present time, the actual area completely stripped is slightly in excess of 7 acres.

The average cost of stripping, throughout the entire operations from their beginning in 1906, has been, approximately, 32c. per cubic yard; this cost covering only the removal of capping and its conveyance to available dumping ground. Applying this cost to the average thickness of stripping removed and ore uncovered, the cost per ton of ore uncovered is somewhat less than 4c. Stripping operations have been more expensive and difficult in the past than they will be in the future, on account of the very limited area upon which the shovels could work and the expensive tracks it was necessary to build in starting these operations in the narrow cañon. As we develop more room, the rate at which shovels can operate will be increased, and the cost of shoveling correspondingly reduced; but the expected decrease in the actual cost of loading the material will probably be offset by the increased cost of hauling the waste material for greater distances, so that it may be expected that our stripping costs will remain about the same as in the past.

Since the last annual report, we have secured by purchase and lease the surface rights of about 120 acres of ground, outside of our own property, for dumping purposes. Of this total area, 75 per cent. was acquired by purchase and the remainder by lease. The total dumping capacity of this surface amounts to 6,330,000 cu.yd., or the equivalent of the capping overlying 50 acres of ore, using the average thickness of 70 ft. so far determined. As a matter of total capacity, the ground already secured will be more than is necessary to accommodate any amount of capping that we will wish to deposit in this vicinity, for the reason that plans are now under way to dispose of the capping in another and profitable manner, as will be hereafter referred to in this report.

MINING

Of the total ore mined during the fiscal period, 33.2 per cent. came from underground, and 66.8 per cent. from steam shovels. During the first six months of the period, the percentages were 39.6 per cent. from underground and 60.4 per cent. from shovels. During the following six months, the percentages were 34.6 and 65.4, respectively. During the six months ending Dec. 31, 1908, the percentages were 28.7 and 71.3. During the last three months of 1908, the percentages of underground and steam shovel ore were 25 and 75 per cent., respectively. These figures are given to indicate the gradual decrease of underground mining; or, more properly, the steady increase in the quantity of ore mined by steam shovels.

The increase in the volume of ore mined by steam shovels is reflected directly in a corresponding decrease in our mining costs. The average cost of both steam shovels and underground ore for the first six months' period above described was 43c.; for the second period, it was 35c.; for the third period, 30c. The average costs stated cover, respectively, the total costs of every nature at the mine, including development, as well as their proper proportions of all general and fixed charges, such as office expenses, taxes and insurance. The average costs for the entire period, as applying to the two different methods of mining, were 66 $\frac{1}{2}$ c. per ton for all ore mined underground and 19 $\frac{1}{2}$ c. per ton for all ore mined by steam shovel—a saving in favor of the steam shovel method of 47c. per ton.

As has been previously stated, the cost of removing the capping from a ton of ore, as shown by our entire experience in the past, amounts to, approximately, 4c. The net difference in favor of the steam-shovel method, therefore, becomes 43c. per ton; this applying to practically all the steam-shovel mining we have done, as we only mined a few thousand tons by steam shovels before July 1, 1907.

From the beginning of stripping operations to date, the equivalent of 15 acres

of ore has been stripped, and the total cost of all this work has been about \$550,000. It is proper to add to this, however, a proportion of the cost of grading and laying railway tracks about the property and to our dumping grounds for the disposition of capping. The total net cost of such tracks, and of all other construction incident to stripping operations up to date, including general expenses, has been, after crediting retirement fund, approximately, \$285,000. If we charge all the proper proportion of general expenses and 20 per cent. of all the construction costs to the stripping operations, the total cost to date becomes about \$690,000. It would not be proper to charge more than 20 per cent. of these construction costs to the stripping already done, because less than that percentage of the area for which these facilities were provided has been stripped. The 43c. per ton saved on ore mined during the fiscal period by steam shovels, as against what it would have cost to mine the same quantity of ore from underground, amounts to, approximately, \$695,000. It therefore, appears that had we charged the entire cost of all our stripping operations, from the date of their inception in 1906 up to the present time, against the steam-shovel ore recovered in 18 months only, it would still have been more economical to mine by the steam-shovel method than by the underground method; or, considered in another way, we have stripped 15,000,000 tons of ore, and have mined only slightly more than 10 per cent. of that quantity with steam shovels, but the entire cost of stripping the total quantity of ore could be charged against the mining of one-tenth of it and still the result would show the steam-shovel method of mining our ores to be the more economical.

Our costs of steam-shovel mining will decrease, rather than increase, in the future, and it is consequently quite evident that our best interests lie in decreasing as rapidly as possible the scope of underground mining and correspondingly increasing our steam-shovel output. It will be necessary, for some years to come, to do some underground work, but we will probably be mining fully 90 per cent. of our ore with steam shovels by the end of 1909, and the underground method, as applying to anything but the development and mining of isolated, and comparatively small, bodies of ore, will be gradually, and as rapidly as possible, discontinued.

Up to the present time, surface-mining operations have been seriously hampered by our inability to secure from the company transporting our ores to the mills an adequate and regular supply of cars, such as to enable us to continuously and most economically operate our ore shovels. Our surface workings have been developed to such an extent that by the end of 1909 we should have no difficulty in

producing regularly 10,000 tons per day, if an additional unit to the Garfield plant should be decided upon, thus bringing our milling capacity up to the tonnage stated. In the meantime, we could increase our output gradually to the extent of supplying tonnage for the sections of the new unit as rapidly as they could, in all probability, be completed.

The ores that have been mined up to date by steam shoveling have not been as high grade as the normal average of the property, because of the necessity of including with them considerable quantities of the partially oxidized and lower-grade capping. Before steam-shovel operations were begun, some parts of the area where we are now working were mined out for a thickness of 20 to 40 ft., along or below the dividing plane between capping and ore. As this mining was done

—the principal one being that by this method of mining our operations will slowly, but gradually, become more economical, and, in the end, we will have recovered 100 per cent. of our ores; whereas, by any other method of mining, it would be impossible to avoid losing a considerable percentage of them.

EQUIPMENT

Since our last annual report, we have added to the mine equipment 2 steam shovels, making 8 in all; 2 locomotives, making 17 in all; and have extended our railroad tracks for mining and stripping purposes to a total of 9.2 miles. During the year 1909 we shall add to our present equipment at least one more shovel and two more locomotives, and shall construct about 6.8 miles of additional standard gage railway for handling capping.

ber, 1908, prepared to handle. Had we been able to secure tonnage, the sections of the plant could have been started up more rapidly and the entire plant put in commission at an earlier date.

Copperton Plant—The Copperton plant also suffered from a deficiency of tonnage, but not to the extent that applied to the Garfield plant, partially for the reason that it is closer to the mines. Of the total tonnage treated at both mills during the period, 83 per cent. went to the Garfield mill and 17 per cent. to the Copperton mill.

PRODUCTION

The total gross output of copper at both plants for the period was 56,895,998 lb. of copper contained in concentrates, resulting in a net production of 54,051,212 lb. after smelter deductions were made. The

LONGITUDINAL SECTION AND PROJECTION OF UTAH COPPER COMPANY'S BINGHAM MINING PROPERTY

by caving, the capping settling into the slopes increased the irregularity of the line between ore and capping, and made it impossible to keep the underlying ore as clean as we would have otherwise been able to do. Moreover, aside from this occurrence, which has aggravated the condition, the dividing line between ore and capping is naturally very irregular, and it is impossible to entirely remove all the oxidized material without wasting some good ore. It is, therefore, necessary to continue taking some of this low grade material into the ore, until such time as the first cut from the top of the ore has been removed over a considerable area; in fact, this condition will always apply to newly stripped areas. This feature is the only one of disadvantage that we have encountered in steam-shovel mining, but, in the long run, there will be advantages which will very much more than offset it.

OPERATIONS AT THE MILLS

Garfield Plant—In our last annual report, it was stated that four sections of the Garfield plant were in commission. Four additional sections were started—one each in the months of August, September, November and December, 1907; and the remaining four, one each in the months of March, April, July and November, 1908. During the fiscal period there was in operation the equivalent of 8½ sections for the entire period, or about 71 per cent of the plant. However, the difficulties experienced in obtaining tonnage for the plant, principally through the lack of proper transportation facilities and services, resulted in our being able to provide only 77 per cent of the rated capacity of that part of the plant prepared for continuous operation, as above stated, or about 75 per cent of the capacity that the plant has and has been since Novem-

ber, 1908, prepared to handle. Had we been able to secure tonnage, the sections of the plant could have been started up more rapidly and the entire plant put in commission at an earlier date.

Of the total gross production of copper above mentioned, 43,873,918 lb. were produced in the 12 months of 1908, this being 77 per cent. of the total for the period. Dividing the 18 months into periods of 6 months, the respective productions were as follows:

	Pounds.	Per Cent.
July 1 to Dec. 31, 1907.....	13,022,080	23
Jan. 1 to June 30, 1908.....	20,096,329	36
July 1 to Dec. 31, 1908.....	23,777,689	42
Totals.....	56,895,998	100

Had we been able to secure, throughout the period the full capacity of the 71 per cent. average of the Garfield plant that was in operation, we would have produced at that plant alone approximately 62,000,000 lb.—a total, for both plants, of about

71,000,000 lb. for the period; or an average of nearly 4,000,000 lb. per month. If our entire Garfield plant, which is now in operation, could be supplied with its capacity of 6000 tons per day, and its operation should result in the same percentage of recovery we have experienced in the period under discussion, and upon the same grade of ore, the output for both plants would be at the rate of 96,000,000 lb. for 18 months; or an average of $5\frac{1}{3}$ million pounds per month, corresponding to a production of 64,000,000 lb. per annum. This is what we may expect to do in the immediate future, provided transportation for the required tonnage can be supplied; in fact, we can do somewhat better than this on the same grades of ore, if we can have transported all the tonnage needed, as the Copperton plant can also take more tonnage than it has been receiving in the past.

It is to be remembered that the results of the period under discussion have been achieved on an ore containing 4 lb. less of copper per ton than the average normal contents of our ore. In addition to this, because of the low-grade and oxidized material that has been taken into the ore through contamination of the steam-shovel output by capping, the ores have contained an average of fully 5 lb. of their copper contents in oxidized minerals, of which only indifferent percentages could be recovered. Both the grade of ore and the percentage of copper recovered will improve gradually as cleaner ore is procurable, as a result of the extension of completely stripped areas.

COST OF PRODUCTION

The average price applying to our sales of copper for the entire period was 13.2c. The average cost per pound was 8.85c, this being based upon the net pounds of copper resulting after smelter deductions and allowances were provided for, and including all expenses of transportation, refining and disposition of the metal.

The deficiency of tonnage, as applying particularly to the Garfield plant, has resulted in the cost per pound of copper being fully a cent higher than it would have been had we been able to secure full tonnage for even the 71 per cent. of the plant averaging in operation. As formerly stated, we were able to mill only 77 per cent. of the capacity of the portion of the plant in operation. The additional 23 per cent. which we were unable to mill owing to the transportation difficulties before mentioned, could have been treated at little or no additional cost for labor, and, in fact, not so great a cost per ton, because a shortage of ore involves us in more expensive methods of handling it through our ore bins. We, therefore, would have saved the milling labor cost on this additional tonnage, which amounts to more than 1c. per lb. of copper produced. If both plants could have been operated at their fullest capacity, a still

greater reduction would have been made in the per pound cost. Our other costs would not have increased in direct proportion, as, for instance, the mine, if it had been able to load ore continuously, could have done so at a considerably decreased cost per ton.

CAPACITY OF THE GARFIELD PLANT

We have been able to operate the Garfield plant at full capacity only for short periods since it was completed, on account of our inability to transport the tonnage. For a few days at a time, however, we have demonstrated that it can handle continuously a greater tonnage than its rated capacity. This determination has also been checked by the capacity of the individual sections, which have proved themselves capable of treating more than their rated tonnage. No difficulties have been experienced in the operation of the plant, and no changes, other than in the way of unimportant details, have been found necessary. Considering the quality of ore we have been reducing, its operation has been, and is, entirely satisfactory.

POWER PLANT AND WATER SUPPLY

The construction and operation of our own power plant, to provide power for the entire enterprise, has proved of great advantage and economy in many ways. We are assured of a constant and uniform supply of power for continuous operation at all points, and the cost of power at the Copperton plant and at the mines at Bingham has been very much reduced over that applying formerly, when power was generated at Copperton for the operation of that plant and purchased from others for the operation of the mine. As stated in our former annual report, the power plant at Garfield has a greater capacity than is necessary for the operation of our milling plants at their present capacity, and it will, therefore, be unnecessary to provide additional power in connection with another 3000-ton unit at the Garfield plant when such addition is made.

Up to the present time, the springs owned by the company adjacent to the Garfield plant, have produced ample water for any tonnage we have handled, and it is believed that they will furnish sufficient for the full capacity of the plant, without making it necessary for us to resort to the use of our proportion of the water we are entitled to take from the Garfield Water Company. We, therefore, have demonstrated conclusively that our total water supply will be ample for very much greater tonnage than we are now prepared to mill.

TRANSPORTATION

A number of references have been made in this report to the difficulty we have experienced in securing adequate transportation facilities, as provided for under our contract with the Rio Grande Western Railway Company. Our losses, and the disadvantages under which we have oper-

ated, as a result of the failure on its part to give us the desired and necessary service, have been greater than would be indicated by the direct deficiency in tonnage that we desired to mine and mill, but which the railway company was not prepared to transport, for the reason that the tonnages that have been delivered to the mills have been handled at a disadvantage and at an extra cost. We have used every effort to induce the railway people to give us better service, but so far without very much encouraging result, and we have, therefore, located and surveyed a line for a railroad of our own between the mines and mills. This location is shown on the appended map of the Bingham and Garfield territory. Negotiations are now pending, which, if consummated, will relieve the situation and give us the transportation facilities we require. If these negotiations fail, I recommend that construction be commenced on our own railway at an early date.

GENERAL REMARKS

In a former portion of this report, reference was made to a proposed method of disposing of capping. We have found that the 1,705,322 cu.yd. of capping so far removed from our orebodies average not quite 1 per cent. copper. Experiments conducted some years ago, and since verified, demonstrate that the larger part of this copper is contained in such forms as can be extracted by a simple leaching process.

As soon as weather conditions will permit, an open-air plant, of moderate capacity, will be constructed at the Garfield mill, and the proposed metallurgy of this material demonstrated on a fairly liberal working scale. If this experiment proves that our former results along this line of investigation are reliable, it is proposed to build a very large leaching plant in which to treat, along the general lines suggested, the capping removed from the property. The chemicals necessary in the proposed method of treatment should be produced cheaply, as a by-product, at any of the smelters adjacent to Salt Lake City.

The production of crystalline graphite in the United States in 1908 was 3,433,033 lb., valued at \$149,763. In 1907 the production amounted to 4,586,149 lb., valued at \$149,548. Despite depressed trade conditions the output of artificial graphite continued to increase. The total production was 7,385,511 lb., valued at \$502,667, against 6,024,000 lb., worth \$58,800, in 1907. This information is gained from reports collected for THE MINERAL INDUSTRY.

The Barrow Hematite Steel Company at Barrow, England, has recently installed a plant of four large blowing engines driven by the waste gases from the blast furnaces. It is the largest plant of the kind in England.

The Largest Coke-oven Gas Engine Plant

A Practical Plan Whereby a Modern Colliery Can Cover All Its Power Requirements at a Minimum Cost and with Maximum Efficiency

BY J. B. VAN BRUSSEL*

The development of the gas-engine power station at the Anna II mine, of the Eschweiler Mining Company at Alsdorf, near Aix-la-Chapelle, Germany, is a good example of how an up-to-date colliery is able to cover all its power requirements in a practical and economical way by taking full advantage of recent engineering progress. At this colliery, as at most others, the coke-oven gas was used until recently as fuel for boilers, the steam of the latter being consumed by the different steam engines about the works. Each of these comparatively small

to transform 30 per cent. of the calorific value of the gases into power, and, therefore, the total efficiency of a gas-engine plant is practically more than double that of a steam-engine plant.

Fully realizing this fact, the directors of the Eschweiler Mining Company decided to scrap the different steam engines, one after the other, and to erect a large power station of gas engines for driving dynamos. The gas engines were to be driven by coke-oven gas sufficiently free from tar, because a by-product recovery plant was to be provided. A special iron-oxide

to erect larger units. During 1904 and 1905 three engines—two of 1000 brake-h.p. each and one of 1200 brake-h.p.—were erected, and in 1907 two twin-tandem engines each of 2400 to 2600 brake-h.p. were installed, all being of the Nuremberg type. These were followed in 1908 by a further order for two engines of 2000 to 2800 brake-h.p. each, so that the total output now is 14,500 to 15,000 horsepower.

This total output of 15,000 brake-h.p. represents about twice the amount of power formerly produced by the steam plant, and it exceeds to a large extent the

GENERAL VIEW OF THE ESCHWEILER PLANT AT ALSDORF, GERMANY

steam-engine plants needed special spare engines, and, in consequence, the maintenance and working costs were high. The calorific value of the gas was thus utilized inefficiently, as a steam engine of the best design is only able to transform into power 15 per cent. (maximum) of the calorific value of the gas, without even reckoning the great condensing loss in the long pipes.

NEARLY ONE-THIRD OF THE CALORIFIC VALUE CAN BE TRANSFORMED INTO POWER. Good gas engines, however, are able

cleaning plant was to be erected for extracting the sulphur from the gas, such sulphur varying in quantity according to the coal used. The installation began with two gas engines of 500 brake-h.p. each, which were ordered from the Maschinenfabrik Augsburg-Nürnberg, for direct coupling to the three-phase dynamo of 500 volts.

LARGER UNITS WERE INSTALLED

The coke-oven gas engines of the Eschweiler Mining Company were set to work during 1904. The engines gave such excellent results that it was decided

power requirements of the colliery itself. Consequently, one part of the current is used at the Edward pit, where the winding engine is driven by means of an 11kV transformer, the current having a tension of 5500 volts. Another part of the power, about 3000 brake-h.p., is transformed from 5500 into 35,000 volts, and is transmitted to the Eschweiler mine, about 11 miles distant, where it is used as auxiliary power for the pit pumps as well as for other purposes.

It is further intended to take about 1500 to 2000 brake-h.p. out of this high-tension conduit to the Maria pit, about 1½ miles

*Brussels, Belgium.

distant. The accompanying photograph shows the gas-engine power station of the Eschweiler Mining Company, which, it is understood, is, or will be—when all the engines now ordered have been delivered—the largest coke-oven gas-engine plant in the world.

The following figures give the results of tests made by Professor Lange, of the Technical University at Aix-la-Chapelle, of the two 2400 brake-h.p. gas engines in Alsdorf. Owing to these tests taking place on a Sunday, it was impossible to

Following these trials, Professor Lange tested one of the engines—designed for coke-oven gas—with the special object of ascertaining how it would work when driven by producer gas made from coke.

Owing to the quality regulation of the contractors, it was proved that the engine was able to work at full load without any alteration of the valves of governing gear, either with coke-oven gas of 340 to 450 B.t.u. per cu.ft. (3000-4000 cal. per cu.m.), or with producer gas of 113 B.t.u. per cu.ft. (1000 cal. per cu.m.). Such results

List of Permissible Explosives

As a part of the investigation of mine explosions authorized by Congress in May, 1908, it was decided by the Secretary of the Interior that a careful examination should be made of the various explosives used in mining operations, with a view to determining the extent to which the use of such explosives might be responsible for the occurrence of these disasters.

The preliminary investigation showed

LONGITUDINAL SECTION OF NUREMBERG GAS ENGINE OF 2800 HORSEPOWER

011 1.07-9.10 E 14 H 15 M.

PLAN SHOWING GENERAL ARRANGEMENT OF GAS-ENGINE PLANT

overload the engines, but preliminary trials had shown an overload capacity of 16 per cent. At the same time the reliable parallel running of the gas engine, combined in every possible manner and under different loads was well proved:

RESULTS OF GAS-ENGINE TESTS.

	Test 1	Test 2.
Output in kw.	1530	1554
Heat consumption guaranteed in B.t.u. per lb.p. and hour 8000		8000
Tested consumption in B.t.u. per lb.p. and hour	6865	6862
Total efficiency, taking the efficiency of the dynamo at 0.815	0.794	0.794
Proved efficiency at full load 0.814	0.837	0.837

would not be possible with the so-called "quantity" regulation which is largely adopted.

The producer-gas plant is erected as an auxiliary plant in case of strikes, or if the coal production and the working of the coke ovens is interrupted for any other reason.

The gas-engine plant of the Eschweiler Mining Company was designed on a large scale, and its actual working proves conclusively the great advantages of large gas engines for an up-to-date colliery.

the necessity of subjecting to rigid tests all explosives intended for use in mines where either gas or dry inflammable dust is present in quantity, or under conditions which are indicative of danger.

With this in view, a letter was sent by the Director of the United States Geological Survey on Jan. 9, 1909, to the manufacturers of explosives in the United States, setting forth the conditions under which these explosives would be examined and the nature of the tests to which they would be subjected.

In response to this communication, applications were received from 12 manufacturers for the testing of 29 explosives. Of these explosives the 17 given in the following list have passed all the test requirements set forth, and will be termed permissible explosives.

Subject to the following conditions, a permissible explosive is defined as an explosive which has passed all the gas and dust-gallery tests. Provided:

1. That the explosive is in all respects similar to the sample submitted by the manufacturer for the test.

(b) The permissible explosives are one and one-fourth to one and three-fourths times as strong, and are said, if properly used, to do twice the work of black powder in bringing down coal; hence only half the quantity need be used.

(c) With 1 lb. of a permissible explosive, or 2 lb. of black powder, the quantity of noxious gases given off from a shot averages approximately the same, the quantity from the black powder being less than from some of the permissible explosives and slightly greater than from others. The time elapsing after firing,

county, and at Black Diamond, in Contra Costa county, were idle throughout the year. The recent developments have been at Lone, in Amador county, and at Stone cañon, in Monterey county. The production in those two counties in 1908 exceeded that of 1907 by 4805 tons, and the increase in value amounted to \$16,627.

The coal-mining industry of California has been adversely affected, first, by the importation of foreign and better coals, brought largely as ballast, and, second, by the increased production of petroleum and its use as fuel in manufacturing establishments. As a result of these conditions the production of coal in the State had decreased from over 170,000 tons in 1900 to 77,050 in 1905, to 25,290 tons in 1906, and to 13,950 tons in 1907. Up to the close of 1908 all the coal mined in the State had been of the lignite or subbituminous variety. During the last year, however, the development of the mines in Stone cañon, Monterey county, has placed on the market a bituminous coal of a quality adapted to compete with the foreign coals brought into the San Francisco market, and it is believed that this will result, to some extent, in the rehabilitation of the coal-mining industry of the State. It is understood to be the intention of the promoters of this enterprise to cater to the domestic fuel trade, in which petroleum does not figure as a competitor.

The production of petroleum in California increased from 33,098,598 barrels in 1906 to 39,748,375 barrels in 1907, and to 44,861,742 barrels in 1908. This enormous output of crude petroleum has almost eliminated coal as a fuel for railroad and manufacturing purposes in California, where it is used almost entirely for domestic purposes. There is promise of additional coal supplies from Monterey and San Benito counties if transportation facilities are procured.

Mine Explosions and Their Causes*

By JAMES TAYLOR†

2. That double-strength detonators are used of not less strength than 1 gram charge consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate (or its equivalent), except for the explosive "Masurite M. L. E.," for which the detonator shall be of not less strength than 1½ grams charge.

3. That the explosive, if in a frozen condition, shall be thoroughly thawed in a safe and suitable manner before use.

4. That the amount used in practice does not exceed 1½ lb. (680 grams) properly tamped.

The above partial list includes the permissible explosives that have passed these tests prior to May 15, 1909. The announcement of the passing of like tests by other explosives will be made public immediately after the completion of the tests for such explosives.

A description of the method followed in making these and the many additional tests to which each explosive is subjected, together with the full data obtained in each case, will be published by the Survey at an early date.

NOTES AND SUGGESTIONS

It may be wise to point out in this connection certain differences between the permissible explosives as a class and the black powders now so generally used in coal mining, as follows:

(a) With equal quantities of each, the flame of the black powder is more than three times as long, and has a pressure 3000 to more than 4000 times that of the permissible explosives. The rate of explosion is slower.

before the miner returns to the working face or fires another shot, should not be less for permissible explosives than for black powder.

The use of permissible explosives should be considered as supplemental to and not as a substitute for other safety precautions in mines where gas or inflammable coal dust is present under conditions indicative of danger. As stated above, they should be used with strong detonators; and the charge used in practice should not exceed 1½ lb., and in many cases need not exceed 1 pound.

Inasmuch as no explosive manufactured for use in mining is flameless, and as no such explosive is entirely safe under all the variable mining conditions, the use of the terms "flameless" and "safety" as applied to explosives is likely to be misunderstood, may endanger human life, and should be discouraged.

Production of Coal in California in 1908*

The total production of coal in California in 1908 was 18,755 short tons, having a spot value of \$54,840.

California is not an important coal-producing State, but it is one of the few in which the output in 1908 showed an increase over that of the preceding year. All of the production was the result of recent developments in new territory. The old mines at Tesla, in Alameda

*Compiled by United States Geological Survey.

Too much reliance is often placed by the management of our mines on the supposed security of ample ventilation. The most disastrous explosions caused by windy, or blown-out shots in the mines of Illinois, have occurred when the ventilation was of superior character. This is natural, as the oxygen in the good ventilating current aids in the quick ignition and embulsion of the carbon-monoxide gas given off by the incomplete combustion of the powder.

The explosive range of marsh gas varies from 6 to 14½ per cent.; the explosive range of carbon monoxide is much wider

*Abstract of paper read before the Illinois Fuel Conference, Urbana, Ill., March 12, 1909.
†State mine inspector.

than this. Carbon-monoxide gas is always found after the firing of shots. This latter gas has much greater power to enlignate a flame than has firedamp, on account of its wider explosive range.

The practice in the majority of the mines of Illinois in getting the coal by blasting off the solid, has little to recommend it. Statistics showing the number of accidents and the coal wasted in Illinois during recent years, are so startling that it is evident there should be a betterment in the present system of mine development. As one who is in constant touch with the practical management of mines, I would advocate the abolition of our present system of blasting coal, as the most effective prevention of mine explosions. Although it is useless at this time to advocate a return to the lump-coal system of mining, nevertheless, I believe such a change would be the surest cure for the reckless use of powder and the lack of proper preparation of shots.

COAL DUST A GREATER ENEMY THAN FIREDAMP

It is universally admitted that coal dust is a greater enemy than firedamp; however, it is a fact that sufficient attention is not always paid to the prevention of its production and accumulation. I believe that this end can only be attained by a proper system of mining and a constant and efficient cleaning of roadways, in preference to the adoption of such systems of sprinkling as are now so generally advocated.

We have had several explosions in our Illinois mines caused by a lack of forethought on the part of the mine management. A violation of the mining law, whereby the miners entered the Zeigler Coal Company's mines, on April 3, 1905, after the fan had stopped, caused an explosion in that mine, killing 50 men. A few weeks ago 28 men lost their lives in this same mine, due to a lack of forethought on the part of the management in not making a thorough examination of all the working places before allowing the men to work therein.

It is unfortunate that unskilled labor is gaining a foothold in the coal mines of Illinois. However, the fact that this is so is before us, and a remedy is needed. It is probable that the best way to correct this evil is to make every man that desires a place as a miner, show that he has previously served an apprenticeship loading coal, before he is allowed to handle powder and prepare shots. Life and property are not safe when in the keeping of densely ignorant and inexperienced men.

If our mine inspectors are to render the most efficient service, they should have the power to discharge and to arrest those violating the law. Having such authority, they could compel obedience to all rules and laws, and establish such discipline as to greatly lessen the danger of accidents.

Tests of Life-Saving Appliances for Mines

BY ROBERT GRIMSHAW*

The experiments here described in detail had for their object to determine how much work a man equipped with life-saving apparatus could do, and to determine the condition of the atmosphere delivered to him. They were made by Wetzke, Christern and Wext of Lubeck; the first a chemist, the latter two, physicians; and were carried out with that thoroughness which characterizes the German scientific investigator—a thoroughness which does not extend to the average German manufacturer or workman.

There was employed to represent the mine or burning dwelling, a workman's house of four rooms in a row; first, a "smoke room;" next a room for the registering instruments; third, a preparation room and the fourth to clean up in.

In the smoke room there were two machines arranged with weights of 20 kg. = 44 lb. each, which should be lifted 1.25 m. = 4.1 ft.; the number of times being registered automatically. Each lift represented 25 meter-kilograms, or 180.825 foot-pounds. Two workmen were employed: Pilz 1.74 m. = 68.56 in. tall, and Holtz 1.66 m. = 65.5 in. Pilz weighed 79 kg. = 174.1 lb. and Holtz, 69 kg. = 152.1 lb. Each was to lift the weight 20 times and then take a rest; so that in each period of work 500 meter-kilograms = 3,616.5 foot-pounds were done.

The tests for carbonic acid were made in about 4 to 5 min. each with a maximum error of $\frac{1}{2}$ per cent.

Four different apparatus were tried: (A) The "Shamrock," from the Maschinen Fabrik Westphalia. (B), (C), (D). Three different apparatus of the Draeger type. In the mouth pipes of the "Shamrock" device, there was 10 cu.in. of air left over; in the "Draeger C," 0.167 liter or 10.2 cu.in. In the new Draeger apparatus D, there was practically none.

The air discharged from the apparatus contained, when no work was done, 2.3 to 2.6 per cent. of carbonic acid; when, however, considerable work was done, the carbonic acid content amounted to from 3.7 to 4.1 per cent. Where the air was held a minute in the lungs, or breathed again and again for the same time, the percentage of carbonic acid was 4.6 to 5.6 per cent.

THE ACTUAL WORK ACCOMPLISHED IN LOWERED BY WEIGHT OF MACHINE

Working in the open air, a man, loaded with the apparatus on his back, performed 43,500 meter-kilograms = 314 foot-pounds of work. In two hours, loaded with the apparatus, but not breathing from it,

his performance was 40,000 meter-kilograms = 289,320 foot-pounds. This shows that the performance of a man is lowered 8 per cent. by the weight on his back.

Considering the best results obtained with the Draeger apparatus (36,500 meter-kilograms = 264,000 foot-pounds in two hours), it is seen that the work was lowered 8.7 per cent. by breathing in the apparatus. If this loss is considered with relation to a less effective apparatus, where for instance only 18,000 meter-kilograms = 130,195 foot-pounds of work were delivered in two hours, the diminishing of capacity is 55 per cent.

There is a general but false impression that the hurtful effect of breathing carbonic acid may be done away with by breathing oxygen; but oxygen has not this property, and its effect on the human body is only produced when the air breathed is free from carbonic acid. The development of the life-saving apparatus shows a constant endeavor to get rid of the CO₂. The workman was capable of full duty only when the carbonic acid was entirely absorbed.

The ability to work when the lungs are impeded by the presence of carbonic acid is different in different persons; so that some persons can do a good hour's work even with the help of apparatus that delivers air charged with carbonic acid. The two workmen who made these tests were chosen from five; the other three having shown themselves unable to go through with the tests with one of the four apparatuses used.

Five to six per cent. of CO₂ may be regarded as causing "bad air;" 11.5 per cent. is characterized as unhealthy; 18.5 per cent. as dangerous; 27.5 per cent. represents the air as breathed out, and is very poisonous, while with 37.5 per cent. CO₂, the air is deadly.

According to statistics collected for THE MINERAL INDUSTRY, the production of iron ore in the United States during 1908 fell off badly, amounting to only 33,781,987 long tons, valued at \$60,821,076, as against 52,955,070 long tons, valued at \$117,560,295, in 1907. The total value for 1908 is figured on an average valuation of \$1.80 per ton of ore delivered at lake ports from the Superior field, or f.o.b. in the other localities. Of the 1908 production 33,781,987 tons came from the Lake Superior region, 20,014,087 long tons from the South and 1,875,000 long tons from other States. All three districts produced less in 1908 than in the previous year, but the South fell off less than either the Lake Superior field or New York and the Central States section.

Pig iron is usually sold at gross tons of 2240 lb., though with a few furnaces the old computation of 2268 lb. per gross ton or "sand ton" still prevails. The gross ton also applies to ferro-alloys. Coke is figured at net tons of 2000 lb. always

*Engineer, Hanover, Germany

Chronology of Mining, May, 1909

May 1—Sale of the Walsh & Seibert coal lands in Indiana for \$1,500,000 to the Equitable Trust and Savings Company, Chicago.—Strike at St. Joseph Lead Company's mines, Bonne Terre, Mo. Mills closed.

May 3—Supreme Court of the United States declared the commodity clause of the Hepburn Railroad Rate Act as constitutional.—Fire broke out in the Forest Hill mine of the Pittsburg Coal Company, Smithdale, Penn.—Fire in North Mahanoy Colliery, Penn., under control.

May 4—Lake navigation opened at Houghton, Mich.

May 5—Pittsburg Coal Company, Westland, Penn., resumed operations after being closed 8 months.—Meeting of representatives of 79 independent coke plants at Uniontown, Penn., to plan consolidation.

May 6—Construction of 560 by-product coke ovens at Gary, Ind., begun by the United States Steel Corporation.

May 7—The Stockton Colliery, Penn., employing 800 men, suspended operations until the fall.—United States Steel Corporation announces the opening of the ore shipping season on the Lakes.

May 9—Fire in the United States Geological Survey's building at Washington, D. C.—Fire broke out in the Dos Estrellos Mines, El Oro, Mexico.

May 11—The directors of the Shannon Copper Company voted to finance the Shannon & Arizona Railroad.

May 12—The merging of the Consolidation, Fairmont, Somerset, Clarksburg, and the Pittsburg & Fairmont Coal companies, and their subsidiaries, controlling 200,000 acres of coal land.—The Ohio Coal Company, Evansville, Ind., resumed operations.—The Cullman Coal and Coke Company incorporated with headquarters at Cullman, Alabama.

May 14—Labor strike at New Idria quicksilver mines, San Benito, California.

May 17—Opening of navigation on Montreal river.

May 18—Murray plant of American Smelting and Refining Company resumed operations after a brief shut-down due to labor troubles.

May 19—Ohio Mining Commission met at Canton to formulate new laws suitable to operators and miners.—Death of Henry H. Rogers, president, Amalgamated Copper Company.—Frick Coke Company started 1000 additional ovens.

May 21—The \$60,000,000 merger of coke plants was completed.

May 22—Largest week's zinc-lead shipment from Joplin district for more than one year.—Price of zinc ore reached \$43.50.

May 23—A silver nugget weighing 3000 lb. was found at Cobalt, Ontario.

May 25—Six thousand miners go on strike in the Kanawha field.

May 28—A formal agreement made whereby the Standard Oil Company will control the Galician oil fields.—Hayden, Stone & Co., purchased control of Santa Rita Copper Company.

Mines as Investments]

By GEORGE D. STONESTREET*

To many laymen the idea of investing in mines seems to suggest gambling, and not legitimate business. Many conservative bankers and staid old business men politely and firmly show the mining promoter the door, and would never allow their names to be attached to any investment where mining is undertaken as a source of revenue. From their point of view such men are correct enough in pronouncing mining a gamble, and in the days before the advent of trained mining engineers they were justified in refusing to look upon mining as an investment. It was usual, 20 years ago, and even now to a smaller extent, to promote a mining property by specious advertisement, untrustworthy reports by alleged experts, and by the sale of stock many times below par value. While it is true that some mines so promoted have succeeded; they have done so in spite of their promotion and management, but 99 per cent. of such promotions usually fail and properly so.

The education of the public on mining matters is important from two viewpoints: (1) That gambling in mines may be stopped, and vast sums of money saved from going into the pockets of unscrupulous promoters; (2) that the public be instructed in careful up-to-date methods of investigating prior to making investment. That such investment can really be called such is a well proved fact today. A mining engineer of standing in the financial world signing a report upon a mine in favorable terms, has the effect of engaging the attention of capital as an investment to the extent of any number of millions which may be required.

Should plain John Smith sign a good report upon a mine, his name, carrying no weight, would have no effect on this class of investors, and ranging between the engineer of international mining fame for skill and probity down to John Smith of unknown skill and doubtful honesty are many thousands of engineers more or less capable. All of the best of these will testify that mining can be made a legitimate investment and can prove their assertion.

Iron and coal mining are today well removed from the promoter's wily ways, and his attention is now usually directed to gold, silver, or copper mining. The following advice may be tendered to the public in mining promotion. When the promoter calls, ask him the following

questions and note that in most cases he will be totally unable to answer them:

(1) Is this a mine or only a prospect?
(2) Should the promoter claim it to be a mine, then ask him how many tons of ore are in sight, who measured them, how the measurement was made, what is the value per ton of ore in sight, how is that value arrived at, and if he has plans of the mine showing its development and value.

(3) Who was the engineer who reported upon the mine, what are his qualifications, and who are his references?

(4) Who are the directors? Have any of them had experience in mining-company directing?

(5) What amount has been spent upon the mine to date, who vouches for this, and what did the property originally cost?

(6) What is the capital stock? How and to whom allotted, and why were they so allotted?

(7) What is going to be done with the money you are now seeking to get out of me, who is going to spend it, who says it will accomplish what you intend it for?

(8) Who is the manager of your mine and what experience has he had to justify his position?

(9) What are the metal contents of ore in the mine, their value, and what process of recovery do you intend to install to recover those metals? Who advises you on this process, and what has been his experience with this class of ores?

(10) What figures have been made to show the probable life of the mine and who made them; in other words, for how many years may I expect dividends, and at what rate?

(11) What title have you? In whose name does the property stand? Is it fully paid for?

He may say, "Your questions are good, but I am only dealing with a prospective mine," and if he says this, it is no investment, but has only a bare chance of becoming a mine. Exploration and development companies should do this prospecting work, for which they are properly equipped, and for which the ordinary promoter certainly is not. Should the promoter claim that he is selling shares only in a prospect then, ply him with questions 3, 4, 5, 6, 7, 8, 9 and 11, and upon the answers being returned, use your best judgment, together with that of some reputable engineer. For just as you would consult your doctor, or your lawyer, so should you consult your engineer. Pay him for his advice and then take it.

In conclusion, a word should be said about a large class of men who put money into mining only for the chance it affords to unload on someone else at a higher figure. They do so without inquiry into the merits or demerits of the property, but these men will be eliminated by a natural process if the careful businessman will act on the advice tendered herewith.

Progress in Cyanidation*

By ALFRED JAMES†

It is rather interesting, if at first sight somewhat disappointing, to note that recent developments in cyanide work have been almost entirely mechanical. And yet that such should be the case is surely a tribute to the band of chemists, prominent among whom were MacArthur and Ellis, who over 20 years ago investigated so thoroughly the chemical side of the process that even today one is forced to acknowledge that chemically the cyanide process stands almost where it did at its introduction.

The use of oxidizers such as atmospheric air, ozone, sodium dioxide, and ferrocyanide of potassium, put forward or investigated by Montgomerie, Moldenhauer, Julian, Kendall and others; the application of alkalis; the use of lead salts now carried to such an extent in the treatment of the silver sulphide ores of Mexico; and even the addition of a granular coating of lead to the zinc shavings, were all recommended or patented in the early days of the process; the use or addition of the halogen salts of cyanogen, including the bromide, iodide and chloride, were all investigated and advocated by Doctor Gaze in New Zealand in the early '90s, and more fully later by Sulman and Teed.

From the earliest days the addition of hypochlorites was investigated in certain quarters (bleaching powder was in actual use on the Kalgoolie field in 1901); but all these accelerators or "improvers," as well as mercuric cyanide (Doctor Keith), and alkaline persulphates including ammonium persulphate patented by Dr. G. A. Schmidt in 1875, have been generally discontinued in practice owing to the increased cost of the improved process without corresponding benefit. The bromo-cyanide process alone may claim to have shown definite and continuous commercial results in practice and it probably would have persisted but for the incidence of cheap roasting which has permitted of higher recoveries at lower cost.

MECHANICAL DEVELOPMENTS

It is on the mechanical side, therefore, that we find most recent developments. And here we are confronted by a change in practice that amounts to a revolution. No longer does one aim generally at crushing an ore as coarsely as possible and with a minimum production of slimed products. On the contrary, the higher recovery obtained from the slimed products has resulted in the adoption of an entirely new method of crushing the ore,

of dissolving out the gold and silver and of recovering the valuable solution from the pulp.

And so passing over the development of the roasting furnaces which now roast refractory telluride and sulphide ores down to as low as 0.01 per cent. of sulphur as sulphide at 2s. 6d. per ton roasted, one comes to the finer crushing of the ore and to that great development of the last few years, the tube mill, the use of which has been publicly stated to be the greatest development in gold-ore treatment since the introduction of the cyanide process. The higher extractions obtainable from the more finely crushed ore are claimed to result in an extra profit of 2s. per ton in South Africa, or say an additional £2,000,000 per annum for that field.

AGITATION

But the finer crushing of ore has led to another development, and that is the circulation of cyanide solutions through the mill, instead of through the leaching plant only, as formerly. This practice is now widely followed in Australia, America and eastern Asia. From time to time, statements accompanied by charts appear in the technical press showing the extra extractions resulting from this practice. As the getting of the gold into solution by percolation in tanks, as of old, is out of the question for a large proportion of the finely slimed product, it has been necessary to effect solution by keeping the pulp in suspension in the cyanide liquor.

This is accomplished naturally during the crushing and transfer of the pulp where cyanide solution is circulated through the mill but the period of contact thus afforded is usually insufficient. Mechanical (paddle) agitators have, therefore, been employed as has also air under pressure—notably by Mr. Moss at the Kalgurli Gold mine—but in practice the latter has proved much too expensive a method and the former has not been entirely satisfactory whether from a mechanical or commercial point of view.

Recently an ingenious modification of the principle of the Pöhlle air lift has been introduced in New Zealand where they use tall tanks in which the lessening of the specific gravity of the contents of an inner tube resulting from the introduction of bubbles of air tends to rapid and most energetic displacement of the pulp contained therein with consequent effective agitation of the mass of pulp contained in the outer tank and surrounding the inner tube. This apparatus has been found very efficient and to require much less power than the mechanical agitator and it has been adopted already in the various great goldfields of the world.

TREATMENT OF SILVER ORES

These notes would be incomplete were I not to refer to the recent great development of the cyanide process in its ap-

plication to the treatment of silver ores. The mechanical developments mentioned above are possibly mainly responsible for this. In the ordinary way, so long a period of agitation is required for the recovery of the silver content of a sulphide ore that the necessary mechanical agitation of the finely slimed ore for some days was found to be a very expensive matter. This time, however, has been very materially reduced by the use of the air-lift system of agitation above referred to and already a large proportion of the silver output of the world is now produced—particularly in Mexico—by the use of tube mills, air-lift agitators and vacuum filtration.

But with the growing tendency to finer crushing and the greater production of slimed pulp, the necessity became more pressing for the provision of a cheap and effective method of recovering the valuable solution from the slimed pulp. In the early days of the process, when confronted with a New Zealand ore which one could not leach in vats, we used filter presses for this purpose and later Ellis treated similar Chilean ore by decantation as the most convenient method available, and until the general adoption of tube mills the mining world was content to treat its slimed pulp by one of these two methods. In West Australia filter-pressing received its greatest development, recoveries of 97 to 98 per cent. of the dissolved gold being obtained at a pressing cost of 1s. 6d. per ton pressed. In South Africa, J. R. Williams worked out a practical method of applying decantation which resulted in some of the highest installations ever erected and possibly the highest recoveries ever obtained in practice by a displacement process.

VACUUM FILTRATION

But with the increased proportion of slimed pulp resulting from the use of tube mills, greater attention has been paid to providing an effective method of recovering a high percentage of the dissolved contents and one is now confronted with perhaps the greatest development in the cyanide process of recent years, the adoption of vacuum filtration. Acting on the basis of the adherence of a mass of filtered cake to a vertical or downward-facing filter until displaced by the discharge of the vacuum or by the application of back pressure, large equipments have been erected (some of them treating upward of 1000 tons of slime per day) for obtaining at a low cost the dissolved contents of the slimed pulp. (Of the success of this latest development of the cyanide process one may judge from the increasing size of the equipments being erected, and from the published statements of a cost of from 3d. to 4d. per ton handled and of a recovery of 99.5 per cent. of the dissolved contents (average for the month of November at a plant treating over 500 tons per day) and from the fact of the

*A paper presented under the title, "Recent Developments of the Cyanide Process," at the International Congress of Applied Chemistry, London, May 23, 1909.

†Consulting mining engineer, 2 Broad Street place, London, E. C.

treatment—if one may rely on published records and statements—of no less than 5,000,000 tons of slined pulp by this process during the last 12 months.

Magnetic Oxide in Matte

BY E. L. LARISON*

For many years an intermittent controversy has gone on regarding a more or less important constituent of copper mattes, magnetic oxide of iron. Some observers go so far as to deny, or at least doubt, its existence.

Although the grounds for such an opinion are surely lacking in many cases, there is no doubt about the fact that a great many mattes when treated with nitric acid do not completely dissolve, but leave a residue of magnetic oxide. This residue often amounts to several per cent. of the quantity taken, and in such cases appreciable amounts can be obtained to work with, and no mistake as to the nature of the substance is credible. The fact of the existence of the residue and its certain identification being established, only one explanation can be put forth in support of the idea that magnetic oxide does not exist as such in the mattes. That is, that it is produced by the action of HNO_3 on the iron sulphide or metallic iron in the matte.

This theory was presented very clearly and with some supporting experimental data by Gibb and Philp.¹ The substance of their argument lay in two points: (1) They show that with increased quantities of oxidizing reagents [HNO_3 and KClO_3] increased quantities of the residue of Fe_3O_4 result on a given matte, showing that at least the amount and strength of the oxidizers have a quantitative influence. (2) The residue of Fe_3O_4 formed in their experiments was soluble in H_2SO_4 , whereas Fe_2O_3 formed at the high temperature of a blast-furnace tuyere region should be very difficultly soluble in H_2SO_4 .

TWO POSSIBLE SOURCES

This theory is somewhat out of the ordinary, as Mr. Keller remarks in his criticism of the original paper. Without going into the theory of the oxidation reactions which might take place, two experimental facts will, nevertheless, have weight. Ordinary FeS which was made by melting together Fe and S and which contains excess Fe and is magnetic, leaves no residue of Fe_3O_4 on being treated with HNO_3 or KClO_3 ; also the Ducktown smelter mattes which are nearly pure Cu.Fe.S combinations, similar to those described by Gibb and Philp, give constant

residues irrespective of the amounts of the oxidizing solvents used. This residual Fe_3O_4 is soluble with difficulty in H_2SO_4 , which, however, does not prove that the Fe_3O_4 was formed in the furnace.

If we grant that Fe_3O_4 does exist as such, in the matte as it comes from the furnace, there are two ways of accounting for its presence. The first is that it is formed in the furnace by action of the blast on the iron sulphides; the second, that it was present in the charge as mineral magnetite and went through the furnace unchanged, in part, at least. The theory of formation in the furnace was brought out very strongly in Doctor Peters' "Modern Copper Smelting," being attributed to high-pressure blast acting on fused FeS . Doctor Peters at that time went so far as to suggest using low-pressure blast produced by fans, and enlarging the tuyeres to admit the necessary amount of oxygen. This theory was pretty well demolished when Mr. Keller pointed out that often reverberatory mattes, produced in furnaces using natural draught, contain large percentages of Fe_3O_4 . Also that the blister copper and the slag from converters, in which exceedingly high blast pressures are found, often contain very little or no Fe_3O_4 . Doctor Peters, in his later "Principles of Copper Smelting," does not speak so strongly as to the formation in the furnace, though he still says that it "may be formed under conditions as yet disputed in both reverberatory and blast furnaces."

UNALTERED MAGNETITE

The alternative, i.e., that the magnetic oxide found in mattes is simply unaltered magnetite which existed in the ores seems a reasonable and natural explanation. It has long been observed that the mattes made by pyritic smelting of the Ducktown heavy sulphide ores always contain magnetic oxide. Recently in making "mineral analyses" of the ores it was found that these ores contain very appreciable percentages of magnetite, and it was this that brought the subject to mind. The evidence which could be obtained with very limited time follows:

There are two ores from mines three miles apart. Both are heavy sulphides, but they differ in some respects mineralogically. I will call them Nos. 1 and 2. No. 1, which produces the ore regularly smelted, contains from 2 to 3 per cent. of magnetite; No. 2 ore contains 12 to 14 per cent. magnetite. The first matte (about 20 per cent. Cu.), made from ore No. 1, contains approximately 3 per cent. Fe_3O_4 , varying from 2 to 3.5 per cent., and apparently the higher percentages with the richer mattes. When this matte is concentrated by putting it through the furnace again, with only quartz and a small amount of coke, a matte is produced. This matte carries

on an average about 5 per cent. of magnetic oxide.

The ore which I have called No. 2 is not regularly smelted at present as it is rather low in copper. But some time ago a test run was made with it for about two weeks, and many matte samples were obtained, running from 5 to 30 per cent. copper. Many samples of different copper tenor were run for Fe_3O_4 , and the amounts varied from 10 to 30 per cent. Only one sample tested, a 4.9-per cent. copper matte, contained less than 10 per cent. Fe_3O_4 .

With these mattes the lower percentages of Fe_3O_4 in general were with the lower-grade mattes until the copper percentage reached about 25, when the Fe_3O_4 appeared to decrease. The mattes were all tested with a magnet. Those made from the No. 2 ore, which contained the high Fe_3O_4 percentages, were distinctly more magnetic than those from No. 1 ore. The corresponding slags were also tested, and again the slags of No. 2 ore were much more magnetic than those of No. 1 ore. I realize that this data is not as full and detailed as it should be to be used in comparison with that of other observers, but it pretends only to be incidental, and it is hoped that it can be made more complete when time allows. However, what little is here presented, I think justifies some generalization.

CONCLUSIONS

It seems clear that the charges which contain the greater amounts of magnetite produce mattes higher in Fe_3O_4 than those from the charges low in magnetite. The mattes, of course, do not account for anywhere near all the magnetite charged, but the fact that the slags in every case are distinctly magnetic, and that this property varies with the magnetite charged, partially at least, accounts for the difference. Also, it is probable that part of the original magnetite is lost by reduction, and combination with SiO_2 . Knowing that there is magnetite in the charges, it is fairer to assume that it partly, at least, goes through the furnace unchanged, than to assume that it is mostly reduced and slagged, and new Fe_3O_4 formed by blast action.

It has been suggested that the difficult solubility of Fe_3O_4 from mattes in H_2SO_4 indicates that the Fe_3O_4 was formed in the furnace at a high temperature. This is offset in the present instance by the fact that the magnetite in these ores is also very hard to dissolve in H_2SO_4 , or even HCl , and the passage through the furnace would not tend to make the solution easier. In the articles that have been published on this subject I have never seen any figures on the magnetite content of the ores from which the mattes quoted were produced. Figures on this point from various ores from different districts would, I think, be of much value in solving the question.

¹Trans., A. I. M. E. Vol. XXXVI, p. 665.

Colliery Notes

With proper equipment, a small peat bog of from 50 to 70 acres will supply a moderate power plant for a good many years. Wet peat with 45 to 50 per cent. of water can be burned successfully in a gas producer; however, the air-dried material of about 25 per cent. water is much more desirable, if the producer process is to go on smoothly and turn out a rich gas.

Artificial wood manufactured from peat is being successfully introduced in Germany. In 1908, peat-wood blocks were used for paving a street at Dresden. Although this street has handled heavy traffic, the trial has showed good results, in spite of the frequent changes of temperature which occurred last winter in Germany. The advocates of this kind of paving claim that the peat-wood blocks are better than asphalt, and that they lessen the noise of carriage traffic equally as well as an asphalt pavement.

According to Arthur E. Taylor, a peat expert of Findlay, O., the peat deposits in Indiana cover about 200,000 acres, or 312 sq.m., and occur in the three northern tiers of counties. The peat beds appear in the sites of old glacial lake basins. Practically all of the workable deposits of Indiana are limited to the counties found in the Lake region, and most of the beds have had their development in these lakes. The filling of these lakes by vegetation undoubtedly began as soon as the ice receded, and is today going on in some degree.

The general idea that marsh gas, so common in coal seams, accumulates and remains in cavities in the roof and higher places of a coal bed, is considerably in error. It is true that this gas is lighter than air, and that as a consequence its presence may sometimes be first noticed in such cavities and high places; however, the accumulation of marsh gas in such places will be only temporary. From the moment the gas is liberated, it is largely governed by the natural law known as "the diffusion of gases," and it immediately begins to mix with the mine atmosphere. In order to prove the foregoing statement, it is only necessary to take two bottles, one filled with ordinary air and the other with methane; connect these bottles with each other by means of a tube passed through a cork inserted in the neck of each bottle; it will be found that after a short interval of time the two gases will have mixed uniformly, and this will occur even though the bottle containing methane is placed uppermost with its neck directed down toward the other bottle.

The question of watering mine roadways has given rise to much discussion. To ascertain the exact effect that sprinkling has on the roof and sides, interesting experiments were recently carried out at

an English colliery. In three distinct seams, a pair of places were driven parallel, about 60 ft. apart; one of the places was watered each working day, that is, five days a week, for three months or more, while the other was left alone. The water was applied with an ordinary greenhouse syringe, about two buckets of water being used on 60 ft. of road; the width of the road was about 12 ft. In the first seam, the measurements showed that in the case of the watered place, the roof lowered, or the floor lifted as much as 14, 7, and 16 in. at three specially selected points; the unwatered place did not alter more than $\frac{1}{2}$ in. In the second seam, the roof of the watered place broke up and fell, at some points, to a thickness of 2 ft.; the unwatered place lowered onto the packs, but did not break up. In the third seam, the roof of the wet place broke up to a height of 20 in., while the dry place remained unaltered.

A careful investigation of the many recent experiments where calcium-chloride has been applied as a remedy for dust in dry mines, shows that this treatment is simple, rapid, inexpensive and efficient; it also facilitates the proper care of distant or inaccessible parts of a mine. In some instances, a solution of calcium-chloride was used, in other cases, a calcium-chloride powder was the agent. It was found that when the solution was applied to the sides or roof, the effect was just as damaging as though water was used. At one mine, 90 gal. of calcium chloride were used to treat 225 ft. of main road; the application kept this part of the road clear of dust for three months. There was no alteration in the height of the road. At another property, 330 lb. of calcium chloride, previously ground to a fine powder, was sprinkled on the entry floor for a distance of 249 ft., no dust having been previously removed. On the following day, the road was wet and no dust arose. When the road was examined two months later, the effect was still visible. Judging from this experiment, one application every three months would be ample. The powdered calcium chloride was sown on dry by hand, 330 lb. being put on 2241 square feet.

A recent invention enables the manufacture of artificial wood from peat. The wet peat is washed without changing the natural fiber, after which the material is mixed with hydrate of lime (water-slaked lime) and with an aluminous combination, and, perhaps, argillaceous earth, the entire mixture being pressed in molds with a pressure of 6400 to 7100 lb. to the sq.ft., the excess of water being released by the pressure. After a short application of the pressure, the board can be taken out of the mold, when it is already very strong and needs only to be completely dried in the open air and worked to the necessary dimensions to be ready for use.

The boards produced by this method can be worked as easily as natural wood, although their strength is much superior to the strength of the natural wood. They can be polished and painted, and according to the statement of the inventor, are 30 to 50 per cent. cheaper than articles made out of good oak wood. The artificial peat wood is suitable for: (1) flooring of every kind; (2) doors, fireproof stairs, ceilings, panels, and all other cabinet work; (3) sidewalks and roof coverings; (4) railroad ties; (5) pavements for streets and factories; (6) complete furniture from the simplest to the most elegant design. The artificial wood is not hygroscopic, and does not require painting or impregnation for use in the open air. The new peat wood is also fungus-proof and very little affected by heat.

Before useful suggestions can be made as to the treatment of coal dust, so as to render it innocuous, it is necessary to obtain some idea as to the rate at which dust is deposited on underground roadways. In this connection, Henry Hall, the English mine expert, recently made valuable experiments in an endeavor to solve this question. With this object in view, aspirators were fixed in a return-air road at intervals of about 75 ft. The action of the aspirator is by means of cotton-wool; the air is drawn through it, and the dust deposited in transit, the cotton-wool being carefully weighed before and after the operation. After collecting data from a number of such experiments, Mr. Hall found that something like 11½ lb. of coal dust were carried in 8 hours past the point where the measurements were taken. The velocity of the current of air carrying this dust was 95 cu.ft. per minute. The result also proved that there was a gradual diminution of the dust as it traveled out-by; there was no traffic on the road on the out-bye side of the point where the aspirator was placed, while the experiments were being carried out. Still other measurements were made, with the object of arriving at the quantity of dust deposited on the floor, sides, etc., as it was being carried along by the ventilating current. In these latter experiments, flat porcelain dishes having an area of 1.12 sq.ft. were used. The time allowed for making the measurements varied from 8 to 10 hours on two separate days. The results of these experiments showed that at the shaft-bottom, where the area of the road is 150 sq ft., 18 lb. of dust are deposited each working day of 12 hours. If it be assumed that this road averages 12 ft. in width and that $\frac{1}{2}$ lb. of dust per lineal foot of such a road is required to make an explosive mixture of dust and air, starting with a clean sheet, it would require 84 ordinary working days to render this 3000 ft. of road at the bottom of the shaft absolutely dangerous. The deposits of dust, of course, will be thicker near the shaft than farther in.

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, PRES. AND TREAS. ROBERT MCKEAN, SECY.
505 Pearl St., New York.

London Office: 6 Boulevard Street, London, E. C. 4, Eng.
CABLE ADDRESS: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice of discontinuance should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for May, 1909, was 52,000 copies.

June 5, 11,000

June 12, 9,500

None sent free regularly, no back numbers.

Figures are live, not circulation.

Consumption of Spelter in the United States

We have previously, in the JOURNAL for Feb. 27, 1909, reported the production of spelter and zinc ore in the United States in 1908, and the deliveries of spelter for consumption, the figures then given including the production of virgin spelter only. We now reproduce those figures, together with our report for the production of reclaimed spelter, i.e., the metal derived from the resmelting of dross and other waste products.

DELIVERIES FOR CONSUMPTION. (IN TONS OF 2000 LB.)

	1907.	1908.
Stock Jan. 1	4,550	32,883
Production	249,612	210,511
Imports	18,000	12,150
Total supply	273,940	256,425
Exports	563	2,440
Stock, Dec. 31	32,883	25,000
Deliveries:	239,494	228,785
(a) Virgin spelter.		
(b) Reclaimed spelter.		

According to the above figures it appears that the deliveries of spelter for consumption were 239,494 tons in 1907 and 228,785 tons in 1908. We have previously called attention to the probability that the reports from the consumers would fail to show so large a consumption in 1908 as the computed deliveries would indicate. It is impossible, for obvious reasons, to obtain reports from the consumers accounting for the entire consumption, there being so many small concerns which keep no records, or which it is impossible to reach. However, the reports that we have received account for so large a proportion of the total that they afford an excellent indication of the status of the consuming industries, especially inasmuch as they can be compared with the reports of the same concerns for the previous year. Upon this basis we estimate the consumption in 1907 and 1908 as follows:

CONSUMPTION OF SPELTER. (IN TONS OF 2000 LB.)

Purpose.	1907.	1908.
Galvanizing.	150,000	119,000
Brass-making.	44,000	33,000
Sheet zinc.	30,000	27,000
Lead desilverization.	2,600	2,500
Other purposes.	12,800	10,000
Totals.	239,494	210,500
Per Cent.	Per Cent.	
Galvanizing.	62 7	62 2
Brass-making.	18 4	17 2
Sheet zinc.	12 4	14 1
Lead desilverization.	1 1	1 0
Other purposes.	5 4	5 2
Totals.	100 0	100 0

It will be observed that we have revised the figures previously reported for 1907 in order to take into the consumption of reclaimed spelter. The change that we have

made in the figures has been chiefly in the case of the consumption of spelter for "other purposes," later and more comprehensive information leading us to believe that the consumption of this metal for a great variety of miscellaneous purposes is considerably greater than what we previously estimated. It is especially these consumers from whom it is most difficult to obtain statistical reports.

The particularly noteworthy feature about the statistics of consumption in 1908 is the deficiency of the total as compared with the deliveries, the difference being 37,285 tons. At the end of 1908 there were large speculative holdings of spelter, but the amount of such metal remaining at the smelteries was included in the stocks reported by the smelters, the inquiry having been specific in that respect. The difference between deliveries and consumption is to be explained by stocks in second hands, and in manufacturers' yards. It is well known that some of the latter had overbought their immediate requirements, and indeed the last report of the United States Steel Corporation contains a statement that it had on hand at the end of 1908 an increased quantity of spelter as compared with the end of 1907. The deliveries of spelter in 1908 did not fall off very largely as compared with 1907, but the actual consumption was only about 80 per cent. of that of the previous year. There was actually a decrease in the accumulated stock at the smelteries, but there was a large increase in the invisible supply. This situation was, of course, the explanation of the sluggishness of the spelter market during the first quarter of 1909, at which time less than 70 per cent. of the retorts of the smelters of ore were in operation. Since that time there has been a healthy improvement in the demand.

Seismic Disturbances and Colliery Explosions

We have been criticized in the last issue of *Mines and Minerals* for publishing an article in the JOURNAL of Feb. 20, 1909, favoring the theory that seismic disturbances are often accompanied by outflows of gas into coal mines. We did not endorse this theory, but in presenting the article by Mr. Spalding, made some editorial remarks about it as follows:

"An argument on the basis of *post hoc*

ergo propter hoc is inconclusive. Nevertheless, it must be admitted that the coincidence between earthquakes and colliery explosions is such as to warrant careful study of the conditions. In this connection, full credit must be given to James T. Beard, who has for many years been drawing attention to the matter, as the readers of the JOURNAL are well aware. . . .

"This, together with the atmospheric theory, that we have previously discussed, continues to demand the careful attention of colliery engineers. Our propaganda as to the probable effect of atmospheric conditions has led many operators to install barometers at their mines and observe them carefully for warning of approaching low pressure. Such warnings are generally recognized in Europe as being of great practical benefit."

The fact that Mr. Spalding's article had previously been declined by our esteemed contemporary lends no force to the argument that we should not have accepted it. Indeed, we are free to confess that this circumstance did predispose us to the idea that the manuscript might contain something of modern interest. We were fully informed of the history of the manuscript by Mr. Spalding in his first letter, wherefore *Mines and Minerals* need not worry about its veto having been unknown to us. In justice to Mr. Spalding, we shall say now that a large part of his original manuscript was devoted to an elaborate thesis in support of his argument, in which he advanced an interesting hypothesis. We asked him to withhold this portion of his manuscript until further researches could be made and additional proofs presented; and we confined his article to the coincidences between the records of seismic disturbances and the occurrences of colliery explosions. We stated very plainly in our editorial remarks that any *post hoc* argument is inconclusive, but urged that the coincidences have been such as to warrant study of the conditions.

The criticisms of *Mines and Minerals* are not of a character to cause us to recede from this position, which has the endorsement of numerous engineers and scientists in Europe and America. Indeed, there are many who take a far more advanced stand. Thus, Mr. Beard, of Scranton, who needs no introduction to the readers of *Mines and Minerals*, and who is recognized as an expert on the subject of colliery explosions in his recently pub-

lished treatise on "Mine Gases and Explosions" strongly advocates the earthquake theory; and at the recent meeting of the Meteorological Congress at St. Petersburg this subject was specifically under discussion, and several delegates suggested that a seismograph be installed at every mine to record earth movements and thereby warn engineers of the possibility of danger.

The JOURNAL aims to lead the way, and by bringing to the attention of its readers suggestive ideas seeks to develop profitable investigations that will elucidate the truth. The sooner we can discover whether barometric pressure, seismic disturbances and other natural phenomena have a direct bearing on the outflow of gases into mines, the fewer unsolved problems in connection with promoting safety in coal mining will there be. The journal that travels the beaten track will arrive only where others have been. Christopher Columbus had difficulty in convincing the scientists of his day that the earth was round. Every town can produce its citizen who has been consistently opposed to every new idea—street cars, telephones, etc.—and Scranton is undoubtedly one of those towns. Fortunately the mining industry has in the ENGINEERING AND MINING JOURNAL a forum that is freely open to rational discussion.

Extension of Oil Production in California

Notwithstanding the large production—just now overproduction—of petroleum in California, there is plenty of exploration for oil going on. In May there were 462 wells being drilled in the State, and some of these are in new districts or extensions of old districts. Thus a syndicate organized by the head of the Santa Fe railway's oil department has taken over the lands of the Western Mineral Company, comprising 4000 acres of the flat southeast of Sunset. Under the agreement of purchase about \$100,000 is to be spent at once in development. One corner of the ground reaches the Johnson holdings where a strong well was recently brought in. The Kramer Consolidated Oil Company at Kramer on the Mohave desert has met oil seepages at a depth of 2000 ft.; there is also an abundance of gas. This is a new territory.

In San Francisco and Los Angeles

there is at present very little speculation in oil stocks, those owning shares in producing wells not caring to sell while dividends are being paid. When once the value of an oil well is established there is little uncertainty except as to the life of the well.

A Mining Code for Arizona

At the Territorial legislative session this year, several bills were introduced for the creation of the office of Territorial mine inspector. Out of this proposed legislation grew a proposition for a mining code commission, to be appointed by the Governor, to prepare and draft a code of laws regulating metalliferous mining. This commission has now been appointed, consisting of Will L. Clark, of the United Verde Copper Company, as chairman, together with Hon. Thomas Armstrong, Jr., an attorney-at-law of much experience, W. F. Staunton, general manager of the Development Company of America, and Messrs. Kipple and Kimball, who are thoroughly experienced underground miners. This commission expects to report at the next session of the legislature, and in the meanwhile will cooperate with the Committee on Prevention of Mine Accidents of the American Mining Congress. It is gratifying to observe that the seed sown by the latter is thus early beginning to bear fruit.

The Longest Pipe-line

Pipe-line connections have been completed by which it is possible to pipe oil from the Oklahoma wells to New York harbor. Oil has been started on the long journey of 1500 miles, but it had not reached the seaboard yet this week. This is the longest pipe-line in existence in the United States, and indeed in the world. It is not probable that much oil from the Mid-continent district will be brought to the seaboard at present, and the completion of the line seems to be more in the nature of a provision for the future, or for emergencies which may arise. Oklahoma has the most active oilfield in the country at present; moreover its production is increasing, while that of Pennsylvania and West Virginia is decreasing. It may not be long before the western wells will be called upon to supply the seaboard and export demand.

Amalgamated Copper Company

The statement issued by this company for the year ended April 30, 1909, gives the general balance sheet at the end of the year as below:

Investment in securities, etc., representing ownership in copper mines, mining claims, mining plants, reduction works, refineries, coal mines, sawmills, standing timber, water rights, land, etc.	\$156,481,847
Loan to Washoe Copper Co., for smelter construction	7,200,000
Cash and cash assets	3,598,102
Total assets	\$167,274,949
Capital stock	\$153,887,900
Accounts payable	25,865
Dividend No. 39, payable May 31	769,459
Surplus and reserve	12,598,045
Total liabilities	\$167,274,949

The stock authorized is 1,550,000 shares of \$100 each; of which 11,121 shares are unissued. The income statement, as deduced from the balance sheet, is as follows:

Net income for the year	\$ 3,661,980
Dividends 36, 37, 38 and 39—2 per cent. in all	3,077,758
Surplus for the year	\$ 586,222
Balance from previous year	12,068,823
Total surplus	\$12,595,045

The statement says: "The producing companies controlled by the Amalgamated Copper Company, have been operated continuously throughout the fiscal year, with the exception of the Anaconda Copper Mining Company and the Boston & Montana Consolidated Copper and Silver Mining Company. The former was compelled to cease operations for a short period of time at the Washoe reduction works, due to the fact that the railroad companies were unable, on account of severe climatic conditions, to transport a sufficient supply of coke; and the reduction works of the Boston & Montana Mining Company at Great Falls were closed from early in June until the middle of September, on account of damage by flood to the power plant of the company and to the railroads, which transport the ore.

"The copper business, during the period covered by this report, has been dull and the ruling price of the metal has been low. During most of the year, the production ran in excess of consumption, but at the present time deliveries of the metal are about equal to the production. Sales have been made in sufficient amount to practically absorb the accumulated surplus, made in the early part of the year.

"All conditions in the Butte camp during the year, tending toward the successful operation of the different properties, have been quite satisfactory, and the cost per pound of copper produced has been materially lessened. The normal amount of development work has been carried on in all of the properties, and the officials of the different producing companies report that this has been done with very satisfactory results and that in several of the mines, new orebodies have been found at

depth, which had never been encountered on the upper levels.

"The fire in the Anaconda mine, which has been burning for a period of 10 years, has occasioned some inconvenience from time to time, but has not interfered seriously with the operation of the property for any length of time.

"A new shaft on the Belmont claim, belonging to the Anaconda Copper Mining Company, has been put in condition and equipped, and will eventually be connected with the lower levels of the Anaconda mine. This when completed will be used as an auxiliary shaft for the operation of the Anaconda properties.

"The shaft at the Parrot mine has been sunk to a depth of 2000 ft. and cross-cuts to the vein have been made at the 1900- and 2000-ft. levels. While the vein at these depths shows ore of a concentrating grade, it is not equal to the average concentrating grade of the camp, and will not yield a profit at present prices for the metal.

"The Little Mina claim, owned by the Parrot company, has been developed by a shaft which has now attained a depth of 1200 ft., and a shoot of ore of good grade has been developed on the 1000-ft. level. Crosscuts are at present being extended toward the vein on both the 1100- and 1200-levels.

"The shaft at the Gagnon mine, owned by the Trenton Mining and Development Company, is now 2300 ft. deep, and the discovery of new orebodies on the lowest levels has increased the value of this mine.

"The improvements at the reduction works at Great Falls, consisting of a stack 560 ft. in height, with flues and dust chambers, are practically completed, and will shortly be in full operation.

"The sawmills of the Big Blackfoot Milling Company have been operated to a greater extent than during the previous fiscal year, owing to the fact that the mines at Butte, on account of their constant operation, have required a larger amount of timber and the commercial demand, while still far below the average, is showing a gradual improvement.

"The coal mines at Belt, owned by the Anaconda Copper Mining Company, and the mines at Diamondville, owned by the Diamond Coal and Coke Company, have been operated continuously, with very satisfactory results, throughout the year.

"The developments at the Bear Creek coal mines, owned by the Washoe Copper Company, have also been most satisfactory, and a grade of coal is being produced, which compares most favorably with the best Wyoming coal.

"A considerable betterment has been made in the mining and reduction costs by the use of electric power. Electric plants have been installed in the mines during the year and operated with good success, and are planned to do hereafter. All the properties in the mines with this power, construction are now being

made to determine the feasibility and economy of operating all the hoisting plants of the different companies by compressed air, generated by electric power.

"The companies, owned solely or in part by the Amalgamated Copper Company, produced for the calendar year 1908, from their own and custom ores, about 234,000,000 lb. of refined copper, of which amount the Amalgamated Copper Company received the benefit from about 100,000,000 pounds.

Speculation in Copper

We have several times referred to the speculation in copper on the London Metal Exchange, emanating from this side of the water. This speculation is, of course, an old story with the metal houses having foreign connections, but during the last year it has been undertaken to a large extent by entirely outside interests. The latest development is the solicitation of such business by a well known firm of bankers and brokers. The following is part of a circular recently sent out by Hayden, Stone & Co.:

"We desire to call attention to the possibilities presented in the purchase of copper, the metal. Those who wish to buy copper, and do not care to be bothered with the details of handling it, will find it most convenient to buy copper warrants on the London Metal Exchange. Copper is dealt in there much as wheat and cotton are handled in this country. The metal is quoted in London in pounds per long ton, and the contracts call for delivery of what is known as 'G. M. B.' copper, a grade slightly lower than our electrolytic brand. The ordinary unit for trading is 25 tons. The usual contract is for three months, and the commission is 34 per cent. for the round turn on the total amount of money involved. The contract may be renewed for a second three months on the payment of an additional commission of 1/2 per cent. The customary protection required is £5/6 per ton.

The stoping width on the South reef at the Roodepoort United mine has been reduced (*South African Min. Rev.*, March, 1909) from an average of 42 in. to under 30 in. The gold-bearing ore on this reef is only a few inches wide as a rule, and the company is now breaking about 25 per cent. less waste rock than it did formerly; also it is hoisting about 25 per cent. less, and, allowing for sorting, it is milling correspondingly less.

According to *Engineering-Contracting*, April 7, 1909, steam shovel No. 220, on March 2, working in the Empire Construction district, central division of the Isthmian Canal, removed 3941 cu.yd. of rock and earth in a working day of eight hours.

Views, Suggestions and Experiences of Readers

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

The Smelter Smoke Question

For some years articles, more or less misleading, relating to alleged smelter-smoke damage, have appeared in various journals. No attempt has been made in the past to refute these statements, but with the conclusion of the Bliss suit, directed against the Anaconda smelter, in which the decision was sweepingly in favor of the company, it seems only just to call attention to misstatements of fact. The article appearing in the April number of the *Review of Reviews* is a case in point, and the astonishing position taken by the editor in refusing to correct errors makes it necessary to seek other channels of publicity. The correspondence submitted below requires no further comment:

Editor *Review of Reviews*:

Dear Sir:

In an article in the April number of your magazine, under the title, "Saving America's Plant Food," Guy Elliott Mitchell uses the following language:

"The Western phosphate beds may be considered of further importance by reason of their proximity to the great smelting works of the West—at Butte, Anaconda, Great Falls and other points. These smelters give off poisonous gases, chiefly sulphurous, that are very injurious to vegetation, *absolutely killing all green things for miles around*. It is found, however, that they can be utilized to great advantage by conversion into sulphuric acid, which is the agent used in reducing rock phosphate to superphosphate fertilizer, or, as it is generally termed on the farm, acid phosphate. Thus not only would a substance injurious to vegetation be controlled, but it would be actually employed in fostering plant growth."

I have too great respect for Mr. Mitchell to believe that he would knowingly indorse such a misrepresentation of facts as is contained in the paragraph quoted, and am inclined to think that he has accepted the statement of a prejudiced government official as being true. The following quotation from the opinion of Judge William H. Hunt, of the Circuit Court of the United States, Ninth Circuit, District of Montana, in denying a petition to enjoin the operations of the immense plant of the Anaconda Copper Mining Company, at Anaconda, after one of the most extensive hearings on record, will, I think, conclusively settle the question of the extent of the damage around Anaconda and adjacent country.

"Fortunately, I have been helped to a better understanding of much of the testimony in the record, indeed, of the whole case, by a visit of two days to the valley, during which time I rode many miles in an automobile in various directions from

the smelter. The trip was made in August, 1905, in company with the master in chancery, counsel for complainant and defendants herein, and one or more expert witnesses for the respective litigants. As I had asked the several counsel to call my attention to anything they thought worthy of particular notice, it is fair to say that I had an excellent opportunity to gain a general, though, of course, somewhat superficial, insight into conditions. Upon the first day, which was bright, the smoke from the big stack rose high into the air, and seemed to be carried far away so high that its diffusion would seem to have been too general to do injury to any land; but on the second day the weather was rainy and the clouds were lower. The smoke then was more dense and its stream was carried down toward the Bliss ranch and southerly and northerly for a few miles toward the center of the floor of the valley, and was there dissipated. The trip impressed one main thing very firmly upon me, that neither the eye nor the training of an experienced or scientific agriculturalist was required to ascertain. It was that the allegation of complainant's bill, to the effect that the Deer Lodge valley and the country adjacent to the smelter are barren and desolate, is grossly inaccurate. It is true that the land and vegetation lying within, say, a quarter of a mile of the smelter, is visibly affected. But outside of this limited area there was the appearance of healthy natural conditions of successful cultivation and of such crop growths as are usually seen in the valleys of the State. The harvest was going on; we saw hundreds of healthy-looking shade and fruit trees about farm houses; the grainfields and pastures looked as others in Montana generally do during or just after harvest. We walked over a portion of complainant's place, noticed the foxtail and inferior quality of the grasses growing, and, except for the smoke on the second day, there was nothing in the physical appearance of the complainant's farm or of the valley that indicated unusual or abnormal conditions."

With reference to the use of sulphuric acid for the manufacture of fertilizers, freight rates are so high as to prohibit any such use of the acid for many years to come. In time, undoubtedly, when the extremely rich soils of the arid West, adjacent to phosphate beds, or near the smelters, shall have become exhausted, a market will exist comparatively near at hand,

but until this time there will be no demand for a product that would be gladly furnished if it were possible to dispose of it.

The men in charge of the great smelters of the West are men of keen business discernment who are constantly seeking means of increasing the value of their output and of utilizing waste products. The "wise men from the East" come with ready-made solutions of the problem, but soon learn to appreciate the obstacles confronting the men who have grappled with and overcome even greater difficulties in the past, and who may be counted upon at the earliest possible moment to make a source of profit of that which is now going to waste.

F. W. TRAPHAGEN.

Golden, Colo., April 22, 1909.

Prof. F. W. TRAPHAGEN,

Colorado School of Mines,

Golden, Colo.:

Dear Sir:

We have read with interest your letter of April 22 replying to a statement made by the writer of our article in the April *Review* on the Western phosphate beds. It does not prove possible, however, for us to print your letter, because there is no provision in any of the departments of the magazine for the printing of communications correcting or controverting statements made in previous issues. It is regrettable to have an erroneous statement made in any of our articles, but it is not quite feasible to devote any considerable space in a subsequent issue to a correction of such statement. We thank you very much, however, for allowing us to read your comments on the point in controversy, and would suggest that perhaps the author of the article in question might be interested in seeing what you say about the matter. Guy E. Mitchell may be addressed care of the Geological Survey, Washington, D. C. We return your letter herewith.

Yours very truly,

Editorial Dept., *The Review of Reviews*.

[There has been a great deal of absurdity published with respect to the smelter-smoke question. There has been no suggestion more absurd than the proposed utilization of the sulphurous smoke of Anaconda and elsewhere for the manufacture of sulphuric acid. We have pre-

viously referred to this in the JOURNAL. It is no matter for surprise that a non-technical journal should fall into the error of fathering such a recommendation, but it is indeed a source of regret that such a recommendation should have emanated from the U. S. Geological Survey, even if it be with respect to a matter that does not pertain directly to the geological studies of the Survey. Although the Government, evidently to "save its face," is now having this matter investigated by a chemical engineer who is qualified to express an intelligent opinion, we have no doubt that the latter will be substantially in accord with that of chemical engineers in general, although its phraseology may be tempered so as to pass delicately over some raw places. Amid the flood of absurdities and prejudice in connection with the smelter-smoke question, the work of Professor Traphagen has stood out eminently for its lucidity, rationality and scientific spirit.—EDITOR.]

The Quebec Mining Law

I beg to call your attention to page 1046 of your issue of May 22 in the article on the Quebec Mining Law, wherein you state that in order to obtain letters patent "an expenditure of \$500 must be made for each acre purchased." The manner in which this phrase should read is as follows: "An expenditure of \$500 must be made for every section of 40 or 100 acres purchased."

J. OBALSKI,

Superintendent of Mines,

Quebec, June 3, 1909.

A condensed statement of the terms of the new mining law of the Province of Quebec has been furnished us by Mr. Obalski, as follows:

THE QUEBEC MINING LAW AS IT STANDS

1. The mines are reserved by the Crown on all the Crown lands and on the lands sold or patented for farming or other purposes after July 24, 1880, the owner of the surface having no right whatever thereon except to the damages. The land needed for mining may be expropriated by arbitration process before the Department of Mines.

2. Gold and silver are reserved by the Crown on all the lands, whatever may be the date of the patent.

3. Surface and underground may form one property, but can be separated in order to form two distinct properties, according to the wish of the owner.

4. The whole Province, surveyed or unsurveyed, is open for prospecting, except on territory already alienated for mining.

5. The staking out of a claim can be done only and personally by a prospector holding a miner's certificate. The cost

of such certificate is \$10, good until Dec. 31 in each year.

6. The staking out can be done on claims having an area varying from 40 to 200 acres in unsurveyed territory and on specified lots, from one to two lots, forming a maximum of 200 acres. Within four months of the staking out a mining license must be taken: (a) On unsurveyed territory for the claim as staked out; (b) on surveyed territory for lots or fractions of lots, containing an area of from 1 to 200 acres.

7. In unsurveyed territory the claim must be rectangular in form, with north-south and east-west orientation; and in surveyed territory the mining license will be bounded by lines parallel to the outlines of the lots, and the description must be furnished to the satisfaction of the Minister.

8. No evidence of discovery, assessment works or surveying is required in order to secure a mining license, but a fee of \$10 plus a rental of \$1 per acre per year has to be paid in advance, and the same is renewable, so long as the necessary amount is paid to this department.

9. The mine may be purchased upon payment of \$10 or \$20 per acre, respectively, within or outside of 20 miles in a straight line from railroad in operation, the above being for a full claim or an entire 100-acre lot. The applicant must produce the proof of a mineral discovery, the concession has to be surveyed and an amount of \$500 spent in mining work before the patent can be secured. On Crown land the surface is sold with the mine, and on private land only the underground property, part of the surface being liable to expropriation should same be necessary.

10. All applications and recording must be made through correspondence with the Department of Mines at Quebec until otherwise announced.

11. The prospecting license system has been abandoned, but the actual holders will keep the benefit of the same and will have the right to renew them until Jan. 1, 1910.

Guerrero and Its New Railroads

In the JOURNAL of April 24, 1909, I notice the following from the correspondent at Mexico City: "A notable state road has just been completed from the end of the central line at Balsas, Guerrero, to Chilpancingo."

It may be of interest to know that the road mentioned is to extend from Iguuala on the Mexican Central Railroad in Guerrero to Chilpancingo, the capital of the State. The road is only about two-thirds completed but work is being rapidly pushed at several points and it is expected to be formally opened before the end of the year. I might add that the present administration of Guerrero, headed by Governor Don Ramon Flores, is one of

the most progressive in the whole Republic. The above is but the beginning of a comprehensive system of roads, proposed by the administration, covering the entire state. It is probable that this road will be put through to the coast at Acapulco in the next few years.

A similar road from Iguuala to the old mining center of Taxco, is nearly completed. These are not "roads" in the ordinarily accepted sense. The road from Iguuala to Chilpancingo is 14 ft. wide, rolled with crushed stone, and having maximum grades of 4 to 4½ per cent. In the low country the road is protected by well constructed ditches and in the higher sections by masonry culverts. The construction throughout of the road is in accord with the latest scientific practice.

Guerrero is a state of vast possibilities in her undeveloped mineral resources, to the development of which the lack of transportation is the chief obstacle. The building of these roads, and the liberal attitude of Governor Flores and his administration toward foreigners is a direct invitation to foreign capital.

The "Consulting Engineer" and a Question of Ethics

In the JOURNAL of May 29 a "Subscriber" inquires as to the ethics of a certain transaction involving a question of professional ethics, upon which the JOURNAL made some comments. The latter were quite right upon the basis of the facts as stated. Although no names were published, and there is but little by which to identify the occurrence about which "Subscriber" wrote, I think that I am able to connect it with certain transactions and am in a position to state that the actual facts were in no way as represented by "Subscriber."

N. Y. Z.

New York, June 4, 1909.

[Our comments in the issue of May 29 were based, of course, upon a certain statement of facts. It should be needless to say that they do not apply to any other condition of affairs.—EDITOR.]

According to figures collected for THE MINERAL INDUSTRY, based on reports of all producers, the 1908 domestic output of lead products was as follows: White lead, 116,628 short tons, worth \$10,515,315, against 111,409 short tons, worth \$12,254,990, in 1907; sublimed white lead, 9100 short tons, worth \$1,156,282, against 8700 short tons, worth \$1,026,000 in 1907; red lead, 11,358 short tons, worth \$1,156,282, against 13,370 short tons, worth \$1,778,717 in 1907; orange mineral, 313 short tons, worth \$43,157, against 813 short tons, worth \$123,917 in 1907; litharge, 12,254 short tons, worth \$1,231,206 against 14,769 short tons, worth \$1,624,553 in 1907.

Conservation of Natural Resources

Progress in Mining and Metallurgy of Iron and Copper. Greatest Waste Is in Use, Not in Production. Engineers and Corporations Defended

BY JAMES DOUGLAS*

In discussing the waste upon which hinges, or is supposed to hinge, so largely the preservation of our national resources, the conclusions reached would be more reliable if actual experience were consulted, and fewer deductions were drawn from general statements, which are often the product of the imagination.

It cannot be questioned that the value of by-products has not been sufficiently appreciated by us, and that our tardiness in recovering the useful ingredients of the escaping gas of our coke ovens is one of the most glaring instances of shortcoming in that direction. And yet even for that sin there is some palliation in the immature condition of affiliated industries. I presume that it is admitted, without argument, that, except under very exceptional conditions, all the elements cannot be recovered from most of the ores or natural products which we treat. While it is a shame that the by-products from our coke ovens should be dissipated, Edward W. Parker's report to the U. S. Geological Survey for 1906¹ supplies a fairly good excuse in justification of this appalling waste. He says (pp. 773 to 774):

"What has been already commented on in previous reports about the slowness of manufacturers to change from the better known but wasteful beehive practice to the by-product-recovery method of coke manufacture is particularly emphasized in the statistics presented in this chapter. For it would appear from the table following that the construction of by-product ovens had about come to a standstill, especially when the records for the preceding five years are taken into consideration. * * *

"One of the reasons that has been assigned for the comparatively retrogressive condition exhibited by the statistics for 1905 and 1906 * * * is the lack of a profitable market for coal tar, and yet the United States is importing coal-tar products to the value of several million dollars annually, while the development of the fuel bricketting industry has been held back because of the lack of assurance of a steady supply of coal-tar pitch for a binder, and users of creosoting oils for the preservation of timber complain of an insufficient domestic supply of this product of coal-tar distillation."

The truth is that one branch of industry is so dependent upon another that there must be equal progress along the whole line of industrial life, if complete recovery of all the available elements of our natural resources is to be effected. The chemical industry must pace with the mining and metallurgical industry. We may be moving too slowly in that direction, but we can distinguish a steady movement toward this needful co-operation. It is encouraging, for instance, to find that the waste gases from the furnaces of the Tennessee Copper Company are being turned into sulphuric acid for the manufacture from Southern phosphates of the superphosphates which the fertilizers of the Southern cottonfields need. Failing this mutual relation between the metallurgist of Tennessee and the chemical manufacturer, the blame should not rest entirely upon the metallurgist for wasting that for which, heretofore, he has been unable to find a market. The same justification exists abroad as in this country for similar waste in other branches of industrial activity.

RECOVERY OF BY-PRODUCTS BY LEGAL COMPELSION

It is nevertheless true that legal compulsion alone has driven manufacturers to introduce improvements and economies which were demanded by public safety, and which have redounded to the benefit of the reluctant corporations. In Germany and England the disposal of noxious vapors and noxious liquors has been required of the manufacturers, but their compulsory removal from the atmosphere and the water has resulted in their conversion into useful products, and the building up of new technical industries. An agitation is springing up in the West against the fumes from smelting works being turned loose into the atmosphere. While in some cases the injury done to vegetation may have been falsely attributed to the smoke from metallurgical works, the agitation has been followed by some good results. For instance, the Mountain Copper Company, having been driven out of Shasta county, Cal., by the farmers, has erected chemical works as an annex to its smelter at Martinez, on San Francisco bay. Here, as elsewhere, manufacturers are reluctant to go to the heavy expense involved in abating such nuisances, even though they may know that in the end the abatement will be profitable. As far back as 1881 Mr. Vivian admitted that in recovering 47 per cent of

all the sulphurous acid emitted from his furnaces in Swansea, he condensed 3666 tons of oil of vitriol at a great profit. This valuable asset, though he does not so state, was secured in spite of bitter opposition on the part of those who were ultimately the most benefited by it. One looks with wonderment at the clouds of valuable fumes which float from the New Jersey shore over Staten island to the sea instead of flowing inland as acid to the chemical manufacturers in the neighborhood.

Our industrial development, however, has reached such a state of advancement, especially in the densely-populated portion of the country, that however averse some of us may be to expend a large share of our profits in improvements, designed primarily to relieve the public of nuisances, we must submit whether we will or not. And having obeyed the mandate of the law, not many years will elapse before we come to realize that what we do under compulsion is as much for our own good as for that of our neighbor.

EARLY EXPERIENCE IN ARIZONA

I promised, however, to confine myself in my remarks to matters of experience. I have been identified with the copper interests of the Southwest since 1881. Though the Southern Pacific railroad had only just traversed the territory, mining was immediately stimulated by railroad transportation, and the Copper Queen, at Bisbee, the Old Dominion, at Globe, and the Lezinskys (the predecessors of the Arizona Copper Company) as well as the Detroit Copper Company, were actively at work at Clifton. All three of the most productive districts, therefore, of southern Arizona were being explored, and, through the influence of the railroad, vigorously exploited, at that time. But none of them were situated on the main line, or were linked to the trans-continental road by branches. The Copper Queen was 60 miles from its nearest railroad station, Benson; the Old Dominion was 140 miles from either Wilcox or Bowie; and the mines of the Arizona Copper Company, and the Detroit Copper Company, were 80 miles from Lordsburg. Coke and supplies had to be hauled in and copper teamed out those long distances.

The ores in all three camps were thoroughly oxidized. At the time this was supposed to be a condition of the highest advantage, upon which the only possibility of economical treatment depended; and not without good grounds,

*NOTE. From *Bull.*, U. S. M. B., May, 1909.
*President of Phelps, Dodge & Co., New York.

¹"Mineral Resources of the United States," 1906, U. S. Geological Survey, Washington, 1907.

for the tedious methods of treating sulphide ore, so expensive in labor and fuel, were still practiced. We all, therefore, imagined in our shortsightedness that the day of doom for the copper interests of southern Arizona would date from the transition from oxidized to sulphide ore. Of the three districts, the only prosperous one during the succeeding 15 years or so was the Warren, and for reasons which we now more clearly appreciate than we then did. The ores of the Copper Queen, or rather such of them as were then selected for treatment, were self fluxing. They contained about 10 per cent. of copper. The slags of that period, which we are now resmelting, contained about 2.5 per cent. of copper. Assuming the slags to represent 65 per cent. of the charge, about 16 per cent. of the total copper content was being stored away in them. Less favorable conditions, however, existed at both Globe and Clifton. The ores of both these districts were extremely silicious, and the furnace charge of ore had to be diluted with from 40 to 50 per cent. of limestone. The silicious ores as treated were probably of about 12 per cent. The furnace charge was reduced by fluxing to between 7 and 8 per cent. of copper. The old slags—65 per cent. of the total charge—yield at Globe about 3.5 per cent., and therefore must have carried from 30 to 32 per cent. of the total copper fed into the furnaces. We have re-treated all the old slags of the Detroit Copper Company, at Morenci, near Clifton, and know that they carried on an average 4.5 per cent. of copper, and must, therefore, have contained at least 40 per cent. of the copper in the ore. At neither Clifton nor Globe was the dust collected, which probably represented a loss of another 5 per cent. Considering the high cost of fuel and labor, it is not to be wondered that neither the Old Dominion, the Arizona Copper Company, nor the Detroit Copper Company, was financially successful for the first 15 or 16 years of their existence. It was not until all the richer carbonate ores had been wasted by being largely converted into slags that the companies recognized that their salvation depended upon securing sulphide ores; upon making metallic copper through the medium of matte, and throwing away less copper in their slags. So little, however, was this fact appreciated at first that we all envied the Arizona Copper Company, because it could turn the San Francisco river into its works and granulate and wash away this valuable refuse. And when the Old Dominion mine struck large volumes of water, the company committed the same act of folly, washing its 3.5 per cent. slags into Pinal creek.

DEFICIENCY OF SULPHIDE ORE

Had the companies realized the losses they were incurring and the only remedy applicable, they would have been obliged to close both mines and furnaces.

except at the Copper Queen, where sulphide ores were encountered within three or four years after the mine was opened and were considered a nuisance, heavy sulphides are elsewhere rare. Though the Old Dominion Company has explored its property to the 10th level, between 100 and 200 tons daily are imported from California and Bisbee, the company's own mines producing only about 60 per cent. of the sulphur required by the furnaces. And at least one of the Clifton smelting companies is obliged to draw from abroad by railroad about 160 tons daily of sulphides high in sulphur and low in copper. It follows, therefore, that there was no alternative in the early days between either suspending operations or making copper in the wasteful manner which the companies then pursued.

Looking at the situation from the standpoint of today, if we place the advantages and disadvantages side by side, we have on the side of the advantages:

1. The experience which was gained during that long period of adversity, which is now being turned to good account, not only by the original companies, but by the many other enterprises which have entered the same field and are profiting by the losses of the pioneers.

2. The southern portion of the Territory has increased in population and in wealth, mainly through the exertions of these copper companies, even while they were losing money on the copper produced. They not only employed thousands of men, but they made a market for the agricultural development of the small amount of arable land within reach of the mines. Had the mines of Globe and Clifton not been operated because pecuniarily unsuccessful, and had not the shareholders been willing to accept hopeful promises in lieu of dividends, Arizona would not today be making an unanswerable plea for admission to the Union as a State.

3. The ultimate success has been due to the advent of the railroad; for railroads are seldom built into unproductive regions in the expectation of creating traffic that does not exist.

ADVANTAGES OF PROGRESS

If we turn to the disadvantages, they are, of course, palpable. At the present time, when we are matting our copper ores instead of making black copper direct, the slags from those three groups of copper furnaces run from 0.4 to 0.5 per cent. of copper. Even when the slags are re-treated, copper in the slags resulting from the slag treatment runs higher than in slags from the treatment of ore, owing to the difficulty of reducing silicates. Thus, when the slags are re-treated, there is a double waste of fuel and the double cost of labor.

It is surprising that our economic systems were different, and that necessity did not induce our corporations to utilize

wastefully the resources they acquire, I think that the balance of advantage to the country at large, as well as to the district, would indicate that it is better to make progress and thereby gain experience, even at the expense of such waste as I above indicate, rather than stand still and do nothing, in the hope of more favorable conditions being brought about by Providence rather than by our own efforts.

NEVER THROW AWAY SLAG OR TAILINGS

Certain lessons, however, the above recital of experience teaches. One of them is, never to throw away anything that contains material of any value, even though it may seem to be valueless. The time inevitably comes when, through improved conditions or better methods, what was waste to one generation becomes of value to another. Most of the filling of the old stopes in the Copper Queen mine and in the Old Dominion mine has already been re-treated. In the case, therefore, of sulphide ore, which is too lean to handle, it should be stored underground rather than exposed to the weather at the surface. I am not sure whether we are justified in ballasting our railroads with the slags which we are making now—lean as they are. One cannot see how 0.5 per cent. of copper and a little gold and silver can possibly be recovered to any advantage, and yet the future may reveal secrets which will convert such impossibilities into possibilities. The slags from the iron blast furnaces, which were deemed valueless a generation ago, are made into hydraulic cement today.

We all recognize the waste that has resulted in the past from washing away gold tailings, which often ran several dollars in gold to the ton. Had they been impounded, the minerals now, through weathering, would be in the fittest possible condition for cyaniding, and would give up to this process their residual values to within a trifle of their contents. The same rule of preservation should be applied to the tailings from copper works. The sulphides, no matter how small their percentage, slowly decay, and give off their copper as soluble sulphate, which can be precipitated on scrap iron at a very inconsiderable cost. If the locality be such that these waste materials can be stored, care, and some outlay, if necessary, should be expended in their preservation.

WASTE IN DOMESTIC LIFE

There seems, however, to be a fascination in contemplating loss rather than saving, and while we cannot exaggerate the follies of waste, it is not fair to the profession to overlook the efforts that have been consistently made within the last three quarters of a century, and are still being made, to eliminate waste. One of the anomalies, however, of the problem is that the accused mining and technical engineers compose the only section of the

public which really appreciates the cost of waste and tries to save.

The recovery of heat units in our domestic fireplaces and furnaces is far less than the recovery of heat from coal burned under our best boilers, when measured as power generated in our steam engines. And the waste in our kitchens and at our tables involves a greater national loss than the waste in our coal mines. In the one case the people at large are making no effort to minimize it, while every technical man of repute is putting his best endeavors into devising means of getting the highest efficiency out of nature's forces, with a view to turn nature's resources indirectly to the greatest good for the greatest number.

* If we look backward to what has happened within our own day and experience, we may justly feel some resentment at the harsh criticism which is now being so generally aimed by the press and the public at technical men. And this is partly true likewise of the strictures so indiscriminately passed upon the corporations which are instrumental in developing the country's natural wealth.

ADVANCES IN IRON MANUFACTURE

In the middle of the last century, less than one-half of the iron made in this country was smelted with anthracite, and the balance with charcoal or charcoal and coke.² The devastation of the forests was awful. Pearse³ gives the consumption of wood in Berks county, Penn., in making 19,000 tons of charcoal iron in 1828, 1830 and 1830 at 250,528 cords. To secure this amount about 8000 acres of the finest forest land in the country must have been stripped. In England, where most of the iron was made with coke as fuel, at the same date, and until 1875, there were consumed from 35 to 37 cwt. of coke per ton of pig iron. In 1875, when the Whitwell stove was introduced to heat the blast, the quantity of fuel consumed was reduced by 3 or 4 cwt. By improved mechanical and metallurgical appliances that consumption in the Middlesbrough district is now lowered to 22 cwt.⁴

This saving of fuel in the blast furnace has, in this country as well as in Europe, been effected through the sleepless activity of metallurgists and engineers, by modifying the size and shape of the great iron stacks, increasing and regulating the temperature and the pressure of the blast, and by the introduction of appliances for utilizing the waste heat. The difference between the 37 cwt. of coke formerly needed to make a ton of pig iron and the 22 cwt. now consumed, multiplied by the number

of tons of pig iron made in the United States in 1906, represents a saving (assuming 1.75 tons of coal as required to make 1 ton of coke) of approximately 30,000,000 tons of coal.

BESSEMER AND GAYLEY

The progress along this line in blast-furnace practice has been steady and wonderful, and has culminated in the ingenious device of James Gayley, which still further economizes fuel, by freezing the blast before admitting it to the stove in order to eliminate moisture, and thus supply the stack with a gaseous element of as constant and reliable a composition as the solid elements of fuel and ore.

The advances in blast-furnace practice in the direction of fuel-saving have been great. But they are not as startling or as picturesque as the economies which followed the introduction of the pneumatic method as applied through the mechanical and metallurgical skill of Bessemer, and as developed in the United States through the genius of Holley. We can all recollect the distressing sight, especially in summer weather, of the puddler, stripped to his waist, toiling over his furnace, while burning up from 20 to 27 cwt. of coal, in converting 1 ton of pig iron into puddle bar. Leaving out of the question the fuel used in generating the power for operating the bessemer converters, which, however, is generally recovered from the waste heat of the blast furnace, the amount of coal saved in making bessemer steel instead of wrought iron during the same year of 1906 exceeded 22,000,000 tons.

THE METALLURGY OF COPPER

The metallurgy of copper has benefited as acutely as the metallurgy of iron and steel from the combined science and skill of the mechanical and metallurgical engineers. One recollects distinctly how, in the old brick furnace, a campaign of 10 days, with a daily charge of 10 tons of ore, was looked upon as almost phenomenal; and that from the time we began roasting sulphide ore in heaps until the refined copper was turned out after endless handlings of the mattes, as they were worked up from lower to higher grades, about three months was occupied. Now, by means of mechanical roasting furnaces, large jacketed cupolas, electrical cranes, the bessemer converter and the Walker casting table, the ore is turned into metal in fewer hours than it formerly took weeks, and at the same time almost dispensing with hand labor.

While these industrial changes were going on in the mining and metallurgical fields, the electrical engineer was bringing under control that tremendous force which Faraday investigated as dynamic electricity; and we metallurgists have not been slow to apply it, both to the saving of fuel and other natural resources, and to the conservation of human labor. The

modern rolling mill, in which a motor replaces the small engine and boiler that used to operate the rolls, and the modern electrolytic plant which turns out electrically pure copper, are only the more visible benefits that electricity is conferring. When some of us commenced our technical experience, the deduction in precious metals made by the refiner of copper before any contribution was made to the miner or the seller, was \$60 worth per ton of ore or metal. Under such heavy charges comparatively small amounts of gold or silver were or could be saved. Today, through the application of electrolysis to the metallurgy of copper, about \$8,000,000 in value, which was formerly lost, is now recovered annually and goes into commerce as a by-product; for the world's copper may be assumed to carry an average of \$10 per ton in gold and silver.

ELECTRICAL TRANSMISSION OF POWER

The last application of this mysterious force, by transmitting from stationary engines electric current for the movement of trains, aims at reducing what is certainly one of the most wasteful uses of coal—its consumption in the locomotive for the generation of steam. In distributing our coal supply, the railroad burns from 20 to 25 per cent. of the total production of our coal mines. This will be notably reduced, though to what extent has not yet been determined. But before this desirable consummation is attained, if electrical engineers continue to extend the limits within which long-distance transmission can be applied economically, they will bring the latent, neglected forces of the whole continent to our doors, and the water powers 1000 miles away, as well as the winds and tides, will propel our railroad cars as well as heat our houses. The service which coal now performs will be fulfilled without the expenditure of human labor and the diffusion of so much obnoxious smoke and vapor. Long before our coal supplies are exhausted, even on the most pessimistic calculation, our children will gladly leave the balance in the ground, and charge off to profit and loss some of what we now consider our most valuable natural asset.

DESTRUCTION OF FORESTS

There is no doubt whatever that the destruction of our forests is attended by a host of such terrible consequences that a halt must be called. In the early days at Bisbee, when we were at a distance from the railroad, we, of necessity, almost stripped the hills of their scanty clothing of stunted wood, for we were forced to use wood for the generation of steam. I find from one of the earliest statements that the company burnt about 2000 cords of wood for the year. The hills for miles around were completely denuded, with the result that disastrous floods have ever since almost annually de-

²In the *Iron Manufacturer's Guide* (1866), Lesley gives the total production in 1854 at 724,820 tons, of which 417,125 tons was charcoal or charcoal and coke iron.

³"*Useful History of the Iron Manufacture*," p. 150.

⁴"A Description of Messrs. Bell Brothers' Blast Furnaces from 1844 to 1908," and other papers *Journal of the Iron and Steel Institute*, Vol. LXXXVII, No. 111, 1908.

laged and damaged the town, which is built in the troughs of two converging valleys. As mining engineers we are sensible of the ruin which reckless lumbering involves, and we lower with regret every stick of timber that we bury underground. Nor are we satisfied to bemoan the fact without making some effort to remedy the evil. It has been suggested, and we are trying the experiment, to replace wood by iron. The forests can be restored in time by reforestation, but iron ores cannot be replaced. And, therefore, it is a false economy to attempt to save a reproductive material by substituting one which rusts and cannot be regenerated. Concrete is also being used more and more in mining operations, and against its substitution for wood there can be no objection; but the most notable economy will result from improved methods of mining, especially from the introduction of the caving and slicing systems.

THE CAVING SYSTEM OF MINING

These were introduced into the Cananea mines when Arthur S. Dwight was manager; and Doctor Ricketts and Mr. Kirk have extended the use of the methods and applied them so successfully that less than half the timber is used per ton of ore extracted today than was buried in the mine three years ago. The following table, kindly supplied by Doctor Ricketts, represents the saving which is going on at Cananea, and in many mines where the same method is applicable:

TIMBER CONSUMED PER TON (WET) OF ORE PRODUCED AT CANANEA, MEX.

Period.	Tons Ore Mined.	Feet Tim- ber Used.	Feet per Ton.
Aug. 1, '05, to Jan. 31, '06.	163,039	10,774,342	23.27
Feb. 1, '07, to July 31, '07.	554,473	8,268,682	14.95
Aug. 1, '08, to Sept. 30, '08.	97,510	1,091,837	11.30

While it would be presumptuous to pretend that, as a people, we are economical, and to deny that, under modern corporate control of large national resources, the temptation, under necessity of making large profits, is not betimes stronger than the appeals which conscience makes to subordinate personal gain to the national welfare, I am sure that neither our largest mining and metallurgical companies nor ourselves, as their working agents, are recklessly indifferent to the preservation of those very materials upon which the wealth of the corporations and our own salaries depend. No large corporation would today use an old boiler and slide valve engine with a consumption of 6 lb. of fuel per h.p. hr. in preference to a triple-expansion, cut-off engine which will do the same work with 1 1/2 lb. per h.p. hr. and so on through the whole gamut of operations which these large corporations conduct and which we, as their working agents, advise them to adopt, because we believe them to be the best and most economical methods.

CORPORATIONS UNJUSTLY BLAMED

While public policy may not be the prime motive for saving, every thinking man in a large institution, from the manager downward, takes a pride in knowing that he is saving, and feels a sense of shame when he is conscious of wasting. And in economic life—1 do not speak of social and domestic life—the rules against waste are becoming more and more rigid and are better enforced. The public outcry, therefore, against the large corporations for wasting the natural resources of the nation is unjust in so far as it fails to recognize what they have done and are doing in the direction of conservation, and inasmuch as it gives the working staff of these great corporations so little credit for the marvelous progress the world has made through their instrumentality. They have saved where formerly, through ignorance and inexperience, their predecessors were wasting. With more profound knowledge, and better instruments for observation and investigation, they are patiently unraveling nature's secrets and learning how to turn her forces to human uses. I cited a case of the unavoidable waste of copper ore, of fuel and of human labor in the treatment of the oxidized copper ores of Arizona 20 years ago. The men who were wasting acted upon their knowledge and skill. So now it often happens that in response to the urgent call which modern society makes by fits and starts for enormously increased productiveness of various commodities, the demand can be met only at the expense of waste of nature's resources, of human energy, and even of human life. If a more stable balance could be maintained between supply and demand; if the current of domestic and economic life would run more smoothly; if wealth were not accumulated so easily and spent so lavishly; if those marvelous improvements to which we have referred were not periodically made, which give these irresistible impulses to world-wide human energy, thereby bringing about these oscillations between hard times and good times, between labor dearth and labor surplus; if all these disturbing elements were obliterated, certainly there would be less waste, and possibly there would be more happiness. But it is not our part nor within our power, as mining and metallurgical engineers, to reconstruct society or renovate the world. Yet it is our duty to continue using our best efforts—whether the world recognizes our merits or not—to get the utmost energy out of human life as well as out of the inert material we handle—with the least possible exhaustion of human tissue and the smallest possible waste of mineral or vegetable material.

According to Stone, all the marble used in Argentina's new government building in Buenos Aires will be cut with carbide tools made here.

The Zinc Corporation

SPECIAL CORRESPONDENCE

The report of the Zinc Corporation, Limited, for the 10 months ended Dec. 31, 1908, states that of the period under review, the first two months were employed in construction and the following three months in experimental mining and adjustment of the plant, during which time the working expenses were necessarily high and returns less than in the latter portion of the year.

The total revenue from the concentrates made and from sulphuric acid sales, etc., was £136,398. The prices at which the metals were sold were: Spelter, £20 3s. 2d.; lead, £13 6s. 7 1/2d. per ton; silver, 24 3/8d. per oz. The latest monthly results recorded are those of April, 1909, when 18,090 tons were treated yielding products valued at £19,065, taking spelter at £20. The month's expenditure was £8352; the cost of material treated, £4523, and the estimated profit, £6160.

The directors refer to a convention that has been arranged between the large smelters to limit production of spelter and hope that thereby improved prices will be obtained in the future. In the profit-and-loss account a profit on the year's operations of £25,504 is shown. There was, however, a debit balance from the previous year's accounts of £85,154, which is now reduced by the profit shown above to £59,650.

The report of the general manager gives statistics of the technical results obtained. A total of 131,065 tons of material (Broken Hill tailings) averaging 20.14 per cent. zinc, 5.69 per cent. lead and 8.47 oz. silver were treated for a yield of 47,312 tons of zinc concentrates, assaying 46.35 per cent. zinc, 7.3 per cent. lead and 15.55 oz. silver, and of 2503 tons lead concentrates, assaying 57.3 per cent. lead, 16.3 per cent. zinc and 38.66 oz. silver. The total extractions work out at 84 per cent. of the zinc, 65.3 per cent. of the lead and 74.4 per cent. of the silver.

The working costs from August to December averaged 9s. 4d. per ton. Further improvements in extraction and costs are expected as greater experience is gained.

The Elmore concentrates produced during the period had an average assay value of 43 per cent. zinc, 16 oz. silver and 10.1 per cent. lead. These concentrates, at the average metal prices ruling for the period, were worth 36s. per ton. After being passed through de-oiling furnaces this product was separated into zinc concentrates and lead concentrates. The value of these final concentrates was 49s. 4d. per ton of original Elmore concentrates, thus showing that these latter concentrates were enhanced in value to the extent of 13s. 4d. per ton by the separation. Photographs of the works accompany the report.

Personal

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

E. Dedolph, of Nelson, B. C., has been visiting New York.

Herbert Haas, of San Francisco, has gone to London, on professional business.

S. S. Fowler, of Nelson, B. C., attended the commencement exercises at Columbia University last week.

George R. Stilwell, manager of the Hewitt mine, Silverton, Slocan, B. C., has returned from a trip to England.

Ernest Schmatolla, of London, sailed for New York, May 29. He expects to pass about three months in the United States.

A. E. Drucker, metallurgical engineer, of Aberdeen, Wash., is now in New Zealand, visiting some of the gold-mining districts there.

E. W. Brooks, of Los Angeles, Cal., is now in Seattle and intends to sail shortly for Alaska to examine copper prospects for Seattle people.

J. S. McCord, of Philadelphia, accompanied by a party of capitalists from that city, recently inspected several of the principal mines at Cobalt, Ontario.

James T. Dixon is now general manager of the Vezerooff-Stanley mining concession, his headquarters being at Salaiski Rudnik, in the government of Tomsk, Siberia.

Professor U. S. Grant, of the Northwestern University, has sailed from Seattle for Valdez to study glaciers and the gold and copper prospects on Prince William Sound.

D. G. Wilson, for several years superintendent of the Bankhead colliery, near Banff, Alberta, has been transferred to the Hosmer mines, British Columbia, in a similar capacity.

Herbert C. Hoover, who has been to Korea since leaving America last spring, is again in London. His recently published "Principles of Mining" is meeting with keen appreciation.

M. S. Davys, lessee and manager of several mining properties in the Slocan district of British Columbia, arrived in Nelson, B. C., recently from London, England, after an absence of two years.

Robert H. Shield, president of the Arctadia Copper Company, has been in Boston arranging the final details in the taking over of the old company by the recently organized Michigan company.

Joseph Hermon, formerly superintendent of the Rothschild, and recently manager of the Progress mine, Cobalt, Ont., has taken charge of mines owned by the Donaldson Brothers, on Bloom lake.

Lewis Stackett, general manager of the Heister Mines, Ltd., Crow's Nest Pass,

B. C., will shortly make Bankhead, Alberta, his headquarters, he being also general manager of the Bankhead Mines, Ltd.

James Grant has resigned his position as chief engineer of the Nelson-Jenks Coal Company, at Sand Coulee, Mont., and has accepted a position on the engineering staff of the Amalgamated Copper Company, at Great Falls, Montana.

H. C. Cutler, who has been managing engineer for the Nixon & Wingfield interests for the past four years resigned April 1 on the dissolution of the firm, and has resumed professional practice with offices at Goldfield, Nevada.

E. W. Durfee has resigned his position as general superintendent of the Daly-Judge Mining Company, at Park City, Utah, and has been appointed general manager of the Alvarado Gold Mining Company at Congress Junction, Arizona.

George O. Argall, who has, for several years, been connected with the Iron Silver Mining Company at Leadville, Colo., was, at a meeting of the executive committee held June 3, appointed general manager of the company's properties in place of Waldemar Arens, deceased.

R. G. Drinnan, for years connected with coal mines in the Crow's Nest Pass district, of British Columbia, has resigned as superintendent of the Hosmer colliery to take charge of prospecting work on a large area of coal lands west of Edmonton, Alberta, recently acquired by a Toronto syndicate.

Karl M. Way, formerly with the fuel-testing branch of the United States Geological Survey, has been appointed assistant mining engineer to the Arthur D. Little laboratory of engineering chemistry, in Boston. Perry Barker has been appointed assistant chemical engineer to the same concern.

Allan Gibb, consulting metallurgist to the Tanganyika Concessions, Ltd., left London for Katanga on June 5, accompanied by W. G. Perkins and P. K. Horner, the engineers who will arrange for the immediate erection of the plant for treating 1000 tons of ore daily which has been purchased, and will be shipped to the site selected for the smelting works in Katanga. The plant purchased is intended for treating the ore from the Star of the Congo mine, which will be the first mine reached by the railway that is at present making rapid progress. Mr. Perkins is well known in this country as the builder of the Steptoe Valley reduction works.

Obituary

Zephyrin J. Pequignot, who died in Philadelphia, June 3, aged 63 years, was considered one of the foremost experts in precious stones in this country. He was frequently called in as consulting expert to appraise the value of gems for the Government and for others.

John F. Gibbons died in New York June 5, aged 60 years. He was born in Baltimore and spent much of his life there, removing to New York about 1890. He was prominently connected with the development of the Florida phosphate industry for 35 years, but retired from active business about a year ago on account of failing health. He was vice-president of the Peace River and the Pierce Phosphate companies, and for some years before his retirement was president of the American Agricultural Chemical Company.

Ernest L. Fraleck died at Cobalt, Ont., May 27, aged 33 years. He was born at Belleville, Ont., and graduated from the Kingston School of Mines. He was employed at several Canadian mines as assistant, and later had charge of pyrites mines in Hastings county. When the Cobalt district was opened he went there and took an active part in its development. He was connected with several mines, and for some time past had been superintendent of the Cobalt Lake mine. He was one of the more prominent and promising of the younger Canadian engineers, and his death at an early age is much regretted. He was an active member of the Canadian Mining Institute, and was elected a member of the council at the annual meeting in March last.

Societies and Technical Schools

Colorado School of Mines—At the commencement exercises at Golden, May 29, President Alderson stated that the Walsh research department is to be continued, and that it is not only possible but probable that radium will be produced in Colorado. John Hays Hammond made an address, and an honorary degree was conferred upon him.

Society for the Promotion of Engineering Education—It has been decided to hold the seventeenth annual convention at Columbia University and Pratt Institute, in New York and Brooklyn, on June 24, 25 and 26. These dates immediately precede those of the meetings of the American Institute of Electrical Engineers, the Society for Testing Materials and the American Society of Civil Engineers. The program will include the reports of the Joint Committee of Engineering Societies on Engineering Education by Dugald C. Jackson; of the Committee on Technical Books for Libraries by Arthur H. Ford; of the Committee on Engineering Degrees by William F. M. Goss; of the Committee on Entrance Requirements by Robert Fletcher; besides contributed articles. In addition, a special session will be devoted to the discussion of Engineering Mathematics by the committee of fifteen, appointed at the Chicago meeting of the American Association for the Advancement of Science.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Denver, Salt Lake City, Goldfield, Colbalt, Mexico

REVIEWS OF IMPORTANT EVENTS

San Francisco

June 4—The interest of mining men still continues to be concentrated on the wonderful quartz discoveries at Alleghany, Sierra county, where each week some new rich strike is recorded. The strange thing is that all these strikes are in old mines, and are the result of active development work, mainly by tunnels. It is only of late that much notice has been taken of this old district. Some of the mines there, now becoming enormously productive were located as early as 1851 and 1852. The surface quartz was removed, and little deep development was undertaken by the owners. Many of these claims were patented nearly half a century ago. In one instance claims located in 1854 and worked but a few months, have recently been sold by the son of the original locator for a high price after all these years of idleness. They were patented so that not even assessment work had been done. In the Rainbow claim the ledge has been struck at a depth of 400 ft. below the old workings and is yielding phenomenally high-grade rock. The El Dorado mine is in the center of the group in which the rich strikes have been made. Mr. Wilson, owner of the Sixteen-to-One, thinks the strike in the El Dorado even more important than that in his own mine. The tunnel is in 500 ft. and the vein found is 2 ft. 6 in. wide.

Of the Morning Glory strike, little is known beyond that very rich ore is being taken out by Rohrig Brothers. In addition to these mines the Plumbago, Oriental, Bonanza King, Wonder and Ophir mines have enriched their owners. The latest strike of note is in the Red Star mine which has struck phenomenally rich ore, some of it being worth \$50 per pound. The company has spent \$50,000 in prospecting and has run a tunnel 2100 ft. This is a vein parallel to the famous Tightner. Mr. L. P. Woodbury is the manager of the company.

In a number of mines in California since the passage of the eight-hour law for mines and reduction works, the men expressed their willingness to continue on the old nine or 10-hour system with the same wages. It has been explained to them, however, that the operators had no more choice than the men in this matter and that they would be violating the law if they permitted the men to work over eight hours. So when the men had their wages cut to fit the eight hour schedule

they had only the law itself to make complaint against. In cases where shovellers and others working 10 hours daily for \$2 per day were concerned, no reduction was made in wages though they worked two hours less. But where miners were getting \$3 for 10 hours and were cut 25c. or more per day to suit the eight-hour system, many of them quit work. Many of the shovellers and other \$2 men quit in sympathy, though they got the same pay for two hours less work daily.

At Oroville last week, Judge Sexton granted the motion of the defendant for a non-suit in the action of Churchman vs. Steifer Brothers of the P. B. Steifer Mining Company. Churchman had alleged fraud in the sale of stock and in the management of the mine, saying that money had been misappropriated. The judge could see no testimony offered which warranted the charges. The suit has attracted great attention, there being many stockholders in the company.

Butte

June 2—At the annual stockholders' meeting of the Anaconda Copper Mining Company held at Anaconda last week the following were elected directors: John D. Ryan, F. P. Addicks, H. H. Rogers, Jr., George H. Church, William Rockefeller, U. H. Broughton and Percy J. McIntosh.

The demand of the men for an increase in wages of 50c. per day at the smelter of the American Smelting and Refining Company, at East Helena, was refused by the company last week and the matter of going out on a strike was put up to the men. By a large vote the union decided not to strike and thus averted the trouble which threatened to tie up the works.

H. H. Gerry, Jr., manager of the Missouri River Power Company, and in active management of the negotiations looking to the construction of the Butte & Helena electric railway, states that while arrangements are not fully completed for the construction of the road, work will be begun on it this summer without doubt. The Northern Pacific and the Chicago, Milwaukee & Puget Sound railways are now engaged in a race to secure the most favorable right of way from Missoula westward through the Lolo pass into Idaho. Agents for both companies are on the ground securing consent of the property owners and several condemnation suits have been filed in the district court at Missoula.

The latest development in the affairs of

the Idaho Smelting and Refining Company, which formerly operated the Pan-handle smelter at Sand Point, Idaho, is an adjudication by the United States district court that the company is bankrupt and the appointment of Bruce Blake as receiver of the company. With the assumption of control by the Federal court all other actions against the company are dismissed, and John Mocine, receiver of the company by appointment of the State court is ousted from the control of the company's affairs. This is a virtual victory for President Anderson, who has, from the first, contended that those behind the previous actions brought against the company were actuated by personal motives.

Annual statements of the East Butte and of the Pittsmont copper companies have recently been filed in the office of the county clerk of Silver Bow county. The East Butte report states that its paid-up capital stock is \$2,150,000; assets, \$3,171,036 and liabilities nil. The Pittsmont Company's report states that its paid-up capital is \$30,000,000; assets, \$33,066,595 and liabilities, \$3,635,055.

What is probably the most far reaching suit with reference to land grants ever filed by the Federal Government in the State of Montana has recently been instituted against the Northern Pacific Railway Company. The suit involves about 1800 acres of land in the Missoula and Helena land districts. The complaint filed by the Government alleges that the land at the time it was classified by the commissioners was well known to be mineral in character, but that the commissioners, with intent to defraud the Government, falsely classified it and thus enabled the railway company to obtain patent. While the Government has recently won a case involving the same points in an action to recover certain coal lands, yet that case is now on appeal to the Circuit Court of Appeals in San Francisco and the law involved has not been definitely determined. Should the Government succeed in its latest case, numerous others of the same nature will doubtless be instituted.

Denver

June 4—The development of the coal mines of the State is being seriously hindered by the Government indictments against various companies and individuals for alleged fraudulent entries and other charges. In one instance, parties are charged with filing on 1500 acres of coal

land and then transferring it to a company, the Government officials charging that the former had the transfer in mind when they made the filings. The Yampa coalfield of 1200 square miles, which has just been reached by the Denver, Northwestern & Pacific railway, is but slightly affected, as most of these coal lands were taken up before there was any prospect of a railway. That there have been irregularities, is conceded, but no actual fraud has yet been shown, and it is the contention of mining men that the Government should have made its investigations before it took the people's money and granted them patents, and not waited for years until the coal was rendered available by the advent of a railroad.

The Western Petroleum Company has been formed to sink for oil near Trull, in Routt county, a few miles west of Steamboat Springs, the present western terminus of the Moffat road. Oil was struck near Trull eight years ago, but without a railroad it was useless and the well was capped. The prime mover and manager of this new company is ex-Gov. James H. Peabody, of Denver.

For some months the Government has been removing the greater portion of the gold stored at San Francisco to Denver for safe keeping, and a shipment of \$6,000,000 arrived this week, making a total, it is said, of \$375,000,000 stored in the vaults of the Denver mint. The shipments were entrusted to Wells, Fargo & Co., and were made in steel boxes, guarded by heavily armed men night and day until arrival. The new Denver mint is fitted with all the very latest inventions and improvements for safety, and having in view the elements of possible earthquake, burglary and invasion, the Government evidently considers this city a more suitable point than San Francisco for the safe keeping of this enormous store of gold and silver bullion. The Denver mint was moved from the old to the new building in 1904, and coining was commenced in 1906.

The production of the Cripple Creek district for May is given at 57,835 tons of gold ore, of a gross value of \$1,360,838, the average value per ton being \$23.74. As compared with April this is a decrease of 2300 tons and \$21,632 in value. The Iron Clad mill was closed and no figures were given out by Stratton's Independence mill, which ran at part capacity during the month.

The Leadville output for the month of May of all classes of ore reached 67,000 tons, being an increase of 10,000 tons over the corresponding month of last year. This is due to a number of new properties that started shipping during the month, and also to the increased production from the mines in South Evans gulch. It is reported that the Arkansas Valley plant will blow in two more furnaces during the month of June.

Salt Lake City

June 4—The Conkling Mining Company and Nicholas Treweek have filed an amended reply to the amended answer of the Silver King Coalition Company in their suit in the Federal court over ore alleged to have been mined from the Conkling property. The suit involves more than \$1,000,000 worth of ore from the famous Elephant stoep and the right to mine in that territory. The Wabash company in Park City has made arrangements whereby it will connect its lowest level with the Ontario drain tunnel and work will shortly be resumed in the lower levels of the mine.

Tintic mines during the week ending May 28, produced 189 carloads of ore, as follows: In 50-ton cars, Ajax, 1; Bullion Beck, 3; Centennial-Eureka, 49; Eagle & Blue Bell, 1; Eureka Hill (leasers), 1; Grand Central, 5; Mammoth 12; May Day, 2; Sioux Consolidated, 14; Undine, 1; Victoria, 4; Yankee Consolidated, 2; in 20-ton cars, Beck Tunnel, 3; Brooklyn, 3; Colorado, 30; Dragon Iron, 25; Iron Blossom, 30; North Cliff, 1.

W. A. Kidney, who had charge of the planning of the Ohio Copper mill at Lark, visited the plant last week. He will probably remain until the mill is finished and put in commission, the date of which has been set for the first week in July. Preparations are being made about the property to handle the big tonnage which the mine management expects to produce as soon as the mill is in operation.

A company has been organized by Joseph R. Murdock, of Heber, Utah, to build an oil refinery near Salt Lake City to handle the product of the Pittsburg & Salt Lake Oil Company. The plant will have a capacity to handle about 100,000 gal. per week of the crude product. The plant will consist of refining stills, condensers, agitators, receiving and storing tanks, bleachers and filters. In addition to the refining of illuminating and lubricating oils, the company will manufacture as a by-product candles from paraffin wax.

Formal announcement has now been made of the proposed reorganization of the Newhouse Mines & Smelters as outlined in the JOURNAL of May 22, 1909. Charles A. Moore, of 111 Broadway, New York, together with Frank A. Schirmer and Louis N. Kramer compose the reorganization committee, and security holders who desire to participate in this plan are required to deposit their stock with the Hungarian American Bank, 32 Broadway, New York City, not later than July 1. The cash requirements of the plan are reported to have been fully underwritten.

Goldfield, Nevada

June 4—The town-site controversy, which has been agitated during the last year, involving the ownership of 500 acres of land occupied by the town of Goldfield has

finally been settled, and town-site property claimants can now receive title to their ground provided the same has been improved. A payment will have to be made to the district Judge to cover the expenses of the land, which it is estimated will be at the rate of \$20 for a lot 30 by 100 feet.

District Judge Peter J. Somers issued a communication to the grand jury last week instructing them to investigate the reports of several mining companies against whom suspicion points as attempting to evade the payment of bullion tax. According to the State bullion tax collector, the Florence Goldfield and the Pittsburg-Silver Peak mining companies are two of the chief offenders.

The Southern Pacific Railway Company filed in the land office at Carson, last week, a map of a projected branch line to extend from Twin Falls, Idaho, to a point on the main line of the Southern Pacific near Cobro, Nevada. The road if built will open up land rich in mineral and timber resources in both Idaho and Nevada.

Articles of incorporation of the Hawthorne & Bodie Railway Company were filed with the Secretary of State last week at Carson. Alonzo Tripp, G. W. Fletcher, J. G. Crumley and others are named as directors. The articles provide for a road operated either by steam or electric power between Hawthorne and Lucky Boy, Nevada, a distance of about 16 miles.

The quarterly meeting of the directors of the Goldfield Consolidated was held in New York May 27 when the regular quarterly dividend of \$0.30 per share was declared which amounts to \$1,050,711. Geo. Wingfield succeeds Sen. Geo. S. Nixon as president, Mr. Nixon retiring from the board as a result of the recent sale of his holdings in the company. W. C. Roelker succeeds Mr. Nixon as director and Mr. Wingfield's position of vice-president is now occupied by J. D. Hubbard, of Chicago.

The Nevada-California Power Company has completed its line from Millers to Manhattan and that camp is now enjoying the benefits of electric light and power. The line is also being extended to Round Mountain.

Manager Mackenzie's report for the month of April shows a total production of 19,417 tons of ore containing \$947,542, the net profit derived from which was \$722,175; 385 tons of the above came from the Hampton stoep and gave net returns of \$287,041. The total cost of production was \$6.40 per ton distributed as follows: Stopping, including part of office expense, \$2.82 per ton; development, including portion of office expense, \$1.10 per ton; transportation, 13.3c per ton; milling, \$2.44 per ton; total, \$9.493 per ton. The cost of operating at the new mill was \$208 per ton. The increase in costs was largely due to the heavy ground encountered in the Clermont shaft where the stations and skip sockets were cut. A safety device to pre-

vent overwinding has recently been installed at the Clermont and Mohawk shafts.

Production of the Tonopah district for the week ending May 29 was: Tonopah Mining, 3400 tons; Montana Tonopah, 955 tons; Belmont, 850 tons; MacNamara, 750 tons; West End, 125 tons, and Midway, 100 tons; total estimated value, \$140,000.

Cobalt

June 5—It is expected that the sale by the Provincial Government, of 800 acres of the Gillies Limit will not arouse as much interest, or bring in as much money, as it would have done two years ago. This section of the Limit surrounds the Provincial mine, and has been prospected by the Government for about three years with few encouraging results. The lack of interest is due largely to the poor showing of the Provincial mine, on which about \$100,000 has been expended, while the return from the sale of ore is little more than a tenth of that amount.

Recent developments in the Keewatin formation have exploded many of the theories formerly held regarding its productiveness and depth. In the great majority of cases when the veins reach the Keewatin the values give out, and so convinced were the mining men of its unproductiveness that but little development work was done in this series. Some time ago the lower workings of the Crown Reserve entered the Keewatin, and the ore was found to be fully as good as in the overlying diabase. Last week one of the Nipissing workings went through the Keewatin into the diabase. As the mineral contents of the veins are generally conceded to have come up with the diabase this latter discovery is likely to have an important bearing on the future development of the camp.

On May 28 a new high-grade oreshoot was encountered in No. 5 vein of the King Edward mine, while drifting west on the 80-ft. level. The vein is about 4 in. in width and consists of calcite carrying native silver, while for about 1 ft. on each side, the wallrock is also well mineralized. This is the third discovery that has been made in this mine within a short period.

The Station Grounds Mining Company, which has been purchasing power for two drills, from the Cobalt lake, has decided to stop operation until the Hydraulic Power Company's air is ready for distribution. Prospecting will be carried on in the meantime with the aid of a diamond drill.

Following the discovery of ore in the Beaver mine, the plant, which was destroyed by fire some time ago, will be rebuilt.

For the past nine months the Comagias Mining Company has been carrying on experiments in the smelter at Thorold, to improve the process for the reduction of

Cobalt ores. The plant is now doing such satisfactory work that the company will enter the market for custom ores, in competition with the other smelters. The capacity will be about ten tons of high-grade ore or concentrates a day.

On May 24 another new vein was discovered on the Farah property, making the second discovery within two weeks. The shaft which is being sunk about the middle of the claim is now down 100 ft. When a depth of 125 ft. is reached a station will be cut, and crosscuts run to tap the veins.

The development of the Lawson property by La Rose, is being watched with great interest on account of the remarkable surface showing of the vein. Work is being carried on from an old shaft, sunk by the Silver Leaf, and which, through a mistake in the survey, is located on the Lawson claim. A drift is being run from the bottom of the shaft, and the management expects to encounter the main orebody shortly. The new vein discovered a short time ago, will also be developed from this working.

The framework for the new concentrator at the Colonial mine is being erected and the stamps are already in place. A 5x16-ft. tube mill, to be driven direct from a motor, has been ordered. The power to run the mill will be obtained from the Electric Power Company when its plant is installed, and it is expected that the mill will be ready by that time.

The rush up the Montreal river from Latchford is so great that the Upper Ontario Navigation Company is unable to accommodate all the people. In one week over 800 men made the trip on the company's boats. The transportation of heavy freight is out of the question for the present, owing to the high water, and there are now about 30 cars of freight, on the siding at Latchford, waiting to be unloaded.

Mexico

June 5—Numerous railroad projects in southern Mexico promise to greatly influence the future development of the mining industry of that portion of the Republic. A much needed and important line is projected from San Juan, near Toluca, to the Temescalteepe, Sultepec and Zacauplan districts of the southern part of the State of Mexico. This line would probably be extended to furnish an outlet for the famous Taxco district, now six hours by trail from the Cuernavaca division of the Mexican Central. This road has been concessioned by the Federal and State authorities but the money has not been raised to construct it. The parties to whom the proposition was made contend that the road should be extended to the coast in order to insure profitable operation. This road is very much needed, and the government is desirous of having it built.

Another projected line runs from Puebla south to the Nohestlan coal district, then to an iron-bearing area, continuing to the Pacific at Port Angel. This is backed by European capital interested in the exploration of the coal and iron deposits of Oaxaca. It is assumed that construction on the first section will be commenced this year. The road will serve as an outlet for the extensive antimony deposits near Tlaxiaco, Oaxaca, controlled largely by the Cookson syndicate. There is also a new lead-silver district in northern Oaxaca, near Huajuapam, that would be benefited by the road. The Mexican Southern railway, an English company, has recently purchased the uncompleted line to the Taviche camp and the Oaxaca and Tlacolula line. The first is being rapidly completed to Taviche. The other line will be extended to Tula to serve the Magdalena district and ultimately connect with the Tehuantepec Isthmus line, affording an easy outlet to the Gulf or the Pacific for all of southern Oaxaca. This extension passes near the Tatolopam mining district, one of the richest in the Republic. Another concern held by St. Louis, Mo., parties covers a practical line from Oaxaca to the Pacific coast via the Rio Verde, tapping the Minas Santiago district where there are large deposits of copper and iron. This was originally projected by C. A. Hamilton and associates as an electric line, the power to be furnished from the numerous and ample falls in the Rio Verde.

A Salt Lake City syndicate has a concession for a line from Oaxaca to the coast, and along the coast to Acapulco and Manzanillo. This is in strong hands but its immediate realization can hardly be considered now. It would open up a rich agricultural and mining country. The Tehuantepec road, planned primarily for transcontinental business, is a factor in the opening up of several camps in southern Oaxaca, and has stimulated activity in prospecting in the Isthmus region. Likewise the Pan-American line, along the Pacific coast from the Tehuantepec road to Guatemala has made available several low-grade lead and copper properties, in the vicinity of Tonalá and in Chiapas. The navigation of the Rio Balsas, now being undertaken as an experiment, promises to open up a very rich and extremely isolated mining region. All these projects are of vital importance to the mining of southern Mexico, and the realization of some of them will greatly improve the conditions in this rich mineral zone.

The mining law has passed the Chamber of Deputies in a form very favorable to the mining interests, and it is now before the Senate where it is expected that favorable action will be taken on the essential points of the measure. It is to become effective January 1, 1910.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

General Mining News

Amalgamated Copper Company—At the annual meeting, June 7, J. H. Harding and James Jourdan were elected directors to succeed the late A. R. Flower and the late H. H. Rogers. The other directors were reelected. A statement for the fiscal year was submitted which will be found on another page.

United States Smelting—All of the company's plants, with the exception of the Utah copper smelter, are operating at their full capacity. In California, the Mammoth smelter is now treating 1200 tons of ore per day, producing 3,500,000 lb. of copper per month, which is the highest rate of production ever obtained at the Mammoth smelter is now treating 1200 plant is treating 670 tons daily.

American Smelting and Refining Company—The earnings of the company are said to be at the rate of 8 per cent. per annum on the \$50,000,000 common stock. This is largely the result of the recent recovery in the prices of copper, silver and lead. While the advance in price is small, it has been sufficient to cause an increase in metal production in Mexico, and as a result the plants at Chihuahua, Torreon, Monterrey and Aguascalientes are now operating on an 80 per cent. basis, whereas 60 days ago they were operating only 60 per cent. capacity. El Paso smelter is now operating at 80 per cent. of its capacity, which is the highest of any plant of the company in the United States.

Alaska JUNEAU

Alaska Treadwell—April: 240-stamp mill 30½ days crushed 37,100 tons of ore; estimated value of bullion, \$58,662. Saved 465 tons of sulphurets; estimated value, \$38,647. Working expenses, \$81,133.

Alaska Mexican—April: 120-stamp mill 30½ days, crushed 18,385 tons; estimated value of bullion, \$44,952. Saved 414 tons of sulphurets; estimated value, \$34,300. Working expenses, \$30,057.

Alaska United—April: Ready Bullion claim, 120-stamp mill 30 days; 700-ft. claim, 100-stamp mill 30½ days; crushed 36,297 tons; estimated value of bullion, \$40,670. Saved 575 tons of sulphurets, estimated value, \$33,220. Working expenses, \$60,238.

K. F. KOKWIN

The gasoline derrick, "P. J. Albert," of Seattle, is expected here with miner's

supplies for 47 different points, indicating renewed activity for this important section.

NOME

T. H. Thatcher, manager of the Alaska Banking and Safe Deposit Company of Nome, predicts a greater output for this season than in 1908. Extensive dredging operations at Nome, Kougarok and other points in that vicinity give great promise.

VALDEZ

It is reported that the Guggenheims have acquired a lease on a quartz claim in the Hope mining district, near Cook's Inlet. The property is on the peninsula near the mouth of Palmer creek. Valuable ore deposits are said to exist.

Arizona

PINAL COUNTY

Ray Consolidated—The report issued by the executive committee shows that 21,977,241 tons of ore have been developed on 60 acres, the copper content of which is 46 lb. per ton. About 500 acres display the same character of rock and surface indications as the areas already developed. Transportation facilities are all that could be desired. An excellent site for a mill has been provided near the Gila river.

California

AMADOR COUNTY

Iron Copper—Superintendent Tartratt recently installed new machinery, put up new buildings and started mining work. Some of the ore carries gold and silver as well as copper.

Bunker Hill—After paying its usual monthly dividend this company has about \$65,000 in its treasury. The main shaft will be straightened and repaired.

Garibaldi Placer—This hydraulic mine at Volcano will hereafter be worked by drifting. The clean-up for this season was nearly \$20,000.

BUTTE COUNTY

Shakespeare—This group at Forbestown, has been acquired by M. J. Cooney and B. F. Forbes, of Oroville, and Mrs. H. E. Vail.

Magdalia—Matt Bader has sold to A. E. Smith, for \$20,000 on deferred payments, the mineral on 160 acres of land near Magdalia. Many claims are being opened on the Magdalia ridge.

CALAVERAS COUNTY

Calaveras Engineering Company—This company has been organized at San Andreas by S. R. Fox, T. W. Downer, F. E.

Tiscornia and others, and will work the Eastland-Gray mining properties on the Calaveras river, near Donellan's bridge. Arrangements are being made to install a dredge.

INYO COUNTY

Ruby Silver—J. H. Oliver, of Goldfield, Nev., has made a discovery of ruby-silver ore near Cottonwood Springs, in Death Valley. A number of prospectors have gone to the camp.

Casa Diablo—Forty men are now employed. Much new machinery has recently been installed and the mine has become productive. Clarence Beale is superintendent. The mine is 20 miles north of Bishop.

Greenwater Copper—The shaft is down 1400 ft. and will be continued to the 1500-ft. level in hopes of finding a paying grade of ore.

SHASTA COUNTY

Washington Gold—This company has incorporated at Redding to work the old Washington mine, at French gulch. The incorporators are C. C. Fox, C. L. Watson, Charles Gilzean, Joseph Porter and F. Stabel.

Consolidated Gold Dredging Company—The dredge belonging to this company is being moved up the Sacramento river from Clear creek to Middle creek, where it is supposed better ground exists.

Friday-Lowden Copper Company—This company has been incorporated to operate the Friday Lowden group of claims between the Mammoth and Trinity copper mines. T. H. Benton and John R. Lowdon, of Redding, are the principal owners. Mr. Benton being the president of the new company which controls 15 acres of mineral ground.

SIERRA COUNTY

West Point—This mine near Downville has been bonded by Peckwith & Spalding to a San Francisco company represented by F. M. Phelps. It adjoins the White Bear.

Kate Hardy—Tyler Dudley, who has recently begun working this property at Forest, has broken into the old works, closed 40 years ago, and found excellent ore.

Minne D—L. A. Wagner has bonded this mine and the Gold Cañon at Allegany and set crews of men at work.

Alleghany—Numerous rich strikes continue to be recorded at this place in addition to those of the Sixteen-to-One, El Dorado, Tightner and Rainbow mines

Large numbers of men have gone to that section, which is, however, not a good place for poor men, as most of the discoveries have been made in tunnels which have taken some years to cut.

TUOLUMNE COUNTY

Big Casino—Lee & French, who have a lease on the Two Brothers and Little Sister claims of this company, have put in a hoist and other machinery and the mill is being put in order to crush the ore. The mine is near Groveland.

Colorado

LAKE COUNTY—LEADVILLE

Lillian—The lessees working in both the upper and lower levels of this Iowa gulch property are doing well, and are shipping a fair tonnage of ore running well in gold.

Houston—A tunnel is being driven by lessees on this claim to catch the main orebody. Several pockets of rich gold ore have already been taken out.

Long & Derry—A tunnel is being driven from the foot of the hill to open the ore-shoot worked from the surface in the early days. About 150 ft. is yet to be driven before it is beneath the orebody.

Carbonate Gypsy—The shaft on this claim is now down 450 ft. and is to be sunk 50 ft. farther. The shaft passed through 200 ft. of porphyry and is now in the limestone.

Mikado—A lease has been taken on this Graham park property by local men. The shaft is being retimbered and the machinery overhauled.

Tribune—The vein recently encountered in this Breece hill property has been opened for a distance of 85 ft. and is reported to be of higher grade than when the strike was first made. Preparations are being made for a 50-ton shipment.

Yak Tunnel—A lateral from the tunnel has been started to connect it with the Resurrection No. 1 mine, which has been drained. It is stated that when the connection is made with the Resurrection property the company will probably lease the ground in blocks.

Horseshoe District—Snow is still so deep in this section that active mining cannot be resumed for several weeks. The Hilltop, Last Chance and Belvidere tunnel is working a small force of men, which will be increased as soon as the roads are open.

SAN MIGUEL COUNTY

Tomboy—Reports from London show an estimated production of \$62,000 in gold, with \$36,500 working expenses, leaving an estimated profit for the month of \$26,400.

TELLER COUNTY

Kimball—A concentrating plant for the treatment of the tailings on the site of the old El Paso reduction works near Gillette is being installed by George K. Kimball.

of Idaho Springs, who has secured a lease and will clean up the dumps. The tailings accumulated in the early days of the district when the saving effected by the chlorination process was much lower than by the cyanide process now in use. The dumps have been carefully sampled and the average value per ton is said to approximate \$2.50.

Idaho

IDAHO COUNTY—GRANGEVILLE

Owing to the cold weather in the mountains the snow is melting very slowly. The water supply is low, necessitating the placers closing down.

IDAHO COUNTY—ROOSEVELT

A heavy landslide is reported from this region. The slide started at the Caswell & Curran placer on Thunder mountain and dammed Mule creek.

SHOSHONE COUNTY

Snowstorm—This mine is reported to be increasing its shipments. On June 1 twenty 40-ton cars were ordered to be loaded.

Standard—Reports indicate that a rich orebody has been encountered in the shaft at the 1650-ft. level; the ore is said to be even better than that on the 1450 level.

Gold Cliff—Good ore is reported to have been found on this property east of the Mother Lode company's holdings. The owners of the company are A. B. Rhude, of Murray, and Dr. W. B. Richardson, of Spokane.

Indiana

GREENE COUNTY

Shirley Hill No. 1—This mine has been reopened, and operation commenced after being closed for nearly two years. The mine works nearly 200 men.

SULLIVAN COUNTY

Hymera No. 33—This mine, of the Indiana Consolidated Coal Company, is boasting of having made the best record of any mine in this field since March 1, having been idle only two days in that time, and one of these days was a holiday. Other mines in this county are not experiencing the lull that usually comes the first two weeks in May, and the season so far is the best ever known for this time of the year.

Bellevue Coal Company—This Delaware corporation has been admitted to do business in Indiana under the foreign corporation act. This company proposes to mine and ship coal from this county. The resident office will be in Carlisle with William H. Arnold in charge.

Michigan COPPER

Keweenaw—A series of drill holes is being put down throughout the tract and in this summer the Kearsarge and Osceola

lodes are to be exposed. Operations at the Medora shaft continue on a limited scale to further open the west fissure vein at depth on what is known as the north lode.

Isle Royale—The A shaft, on the Baltic lode, has reached a depth of 425 ft. Copper has been revealed from time to time in the shaft. The shaft is nearing the depth that the lode was cut by the drill core and will probably enter the formation within a very short time.

Quincy—At a depth of about 400 ft. in the No. 9 shaft the formation has deflected and the shaft is going down in the footwall. The copper-bearing portion of the lode passed out of the shaft at a depth of about 210 ft. Drifting in the direction of this shaft from No. 8 shaft is opening good grade of ground.

Franklin—Drifting continues at the 23d, 24th and 25th level of this company's No. 1 shaft on the Pewabic lode with a good grade of copper rock opened throughout. The north drifts are approaching the Rhode Island tract, and indications are that this land carries the underlay and it will be but necessary to sink deeper.

Cliff—Work has been suspended on the Cliff property which is controlled by the Tamarack. The diamond drill near the Ojibway line is under way to expose the Kearsarge lode and this work will be continued.

Montana

BROADWATER COUNTY

Ohio-Keating Gold Mining Company—A gasoline plant has been installed at the property, near Radersburg, with a view to saving on fuel cost until arrangements can be made to use electric power. Water rights have been secured, which will later be utilized for the generation of electricity. John H. Cowan, of Salt Lake City, is general manager of the company and Charles S. Shoemaker, formerly State mine inspector of Montana, is in charge of operations at the mine.

CARBON COUNTY

Butcher Creek Oil Fields—Thomas Cruse, of Helena, has recently acquired all outstanding interests in the district, and is now making preparations for a thorough exploration of the fields. Machinery for drilling has been on the property for some time, but until now conflicting interests have made it impossible to work the property.

CASCADE COUNTY

Great Falls Gas Company—The company has recently purchased from the Northern Montana Coal Company and E. R. Clingan, 2040 acres of coal land, near Belt. It is the purpose of the company to use the lands for obtaining coal to be used in the company's new gas plant now being constructed at Great Falls.

Nevada

CHURCHILL COUNTY—BOYER

It is reported that capitalists from Wilmington, Del., have made a first payment on the Boyer copper property comprising 27 claims located at this point, the sale price being announced as \$250,000. The deposit consists of a porphyry intrusion, mineralized from 30 to 1000 ft. in width. The company will be known as the Boyer Nevada Copper Company; the provisional directors are: Dr. F. R. Carpenter, of Denver, president; H. R. Durkee, of Chicago, vice-president, and Arthur H. Carpenter, of Denver, secretary and treasurer.

ESMERALDA COUNTY—GOLDFIELD

Junio Wonder—This lease on the Poleverde claim of the Junio Extension Company was forfeited some time ago and has been secured by a group of Philadelphia men, among whom are W. D. Hickman and W. F. Rose. A contract has been let for sinking the shaft 200 ft. from its present depth of 250 feet.

ESMERALDA COUNTY—HAWTHORNE

Spencer Lease—A strike of exceedingly rich ore is reported as having been made in this property at a depth of 300 feet.

Elgin, Randall and Cordev Lease—J. C. McCormack, of Goldfield, purchased this lease on the Lucky Boy No. 1 lode last week. The former leasers worked about 60 days and sank their shaft to a depth of 90 ft. through pay ore a greater part of the distance. In the bottom of the shaft there is now exposed 2½ ft. of ore which runs in excess of \$100 per ton.

ESMERALDA COUNTY—MINA

Lucky Man Mine—A strike was made last week on this property situated two miles north of Mina. The vein, 18 in. wide, was encountered in a crosscut from the main tunnel and assay returns run high in gold, silver and lead.

ESMERALDA COUNTY—RAWHIDE

King-Heisner—A large portion of the frame work for the new mill is in place. The telephone line from the water-works to the mill and town is completed.

Grutt Mining—Work has been started at the 100 and 200-ft. levels of the Wild West claim. It is 90 ft. to the shoot of high-grade ore which is being developed so extensively in the Marigold property.

Queen Bethania—A 4-ft. vein of gold-bearing quartz has been encountered. A shaft is to be started and development work carried on extensively.

Steinheimer—Fifty tons of ore from the McMann claim was shipped recently to the Schuy smelter. The ore is said to contain approximately \$85 gold per ton.

LANDER COUNTY—AUSTIN

Pattison—This property located north of Austin has been acquired by the Maricopa Mines Company, of Arizona. The company is a close corporation, and is com-

posed of men from Cleveland Ohio, principal owners being L. F. McGrath, A. J. Rogers, J. F. McGraw and E. A. Richardson. The shaft will be repaired, a new hoisting and compressor plant installed, and operations pursued on a large scale.

NYE COUNTY—BELLEHELEN

Sciota Nevada—It is reported that a steam hoist and ten-stamp mill have been ordered by this company. The property is opened by a 200-ft. shaft, from which laterals have been run, also by a tunnel 600 ft. in length.

NYE COUNTY—BULLFROG

Tramp Consolidated—A fair sized body of ore has been blocked out on the Clothier & Jingles lease. Four hundred sacks of ore averaging \$100 per ton are now ready for shipment. On the Kuliacka-Vincovitch lease work is being pursued on the lode at two different points; the vein varies from 10 to 15 in. in width, the ore ranging from \$60 to \$175 per ton in value. A shipment is now being prepared, to be sent out in June.

Montgomery Shoshone—This property is now producing an average of 200 tons daily. A shipment of bullion was made last week, having a valuation of approximately \$18,000 which was the result of the semi-monthly cleanup.

NYE COUNTY—MANHATTAN

Placers—About 150 men are now operating on various placer deposits in the gulch between Manhattan and the Smoky valley. The daily cleanup is estimated at \$1000. Nuggets worth from \$5 to \$15 have been found, the largest recorded being worth \$22.50. The average yield of the gravel is in the neighborhood of \$10 per yd. The Pneumatic Dredger Company, of Sacramento, Cal., has a machine en route to Manhattan which is expected to handle 500 yd. per day.

NYE COUNTY—PIONEER

Puritan Savage—A strike was reported last week on this property, which is situated about a mile northeast of town. The shaft, which is 85 ft. deep, has encountered a vein of good ore from 4 to 6 ft. in width.

Bullfrog Pioneer Lease—Ore of a high grade has been encountered in the bottom of the winze from the 210-ft. level. Electric power was turned on last week. The production for the week was in excess of \$30,000. About 60 men are now employed at the mine.

Richard Garburg—Ore was disclosed in the tunnel level of this lease last week which assays up to \$40 per ton. Three shifts are now employed and the ore is being sacked for a trial shipment.

NYE COUNTY—ROUND MOUNTAIN

Round Mountain Mining—The production of this company for the first 15 days of May, amounted to nearly \$17,000. Electric power will be furnished the property this month.

NYE COUNTY—TONOPAH

Tonopah Mining—The Mizpah shaft is now down to a depth of 1386 ft. A cross-cut is being run at the 1380-ft. level and a sump will be cut about 20 ft. from the shaft, and the water from above will be collected at this level. The compressor has been found inadequate for the demands made upon it, and another has been ordered. The 150-h.p. hoist at the Mizpah shaft has been replaced by a 300-h.p. electric hoist which handles the load easily. The mill report for week ending May 22, shows 3225 tons of ore crushed; average value of \$20 per ton; 64 bars of bullion, valued at \$850 per bar, and 27 tons of concentrates at \$425 per ton were shipped.

WHITE PINE COUNTY

Cumberland-Ely—According to a circular issued by a New York brokerage house, the investment of this company in the Steptoe reduction works is \$3,000,000, on which it has a guarantee of 8 per cent. In addition, Cumberland-Ely is said to be receiving \$300,000 per annum as its half share of the net earnings of the Nevada Northern Railroad. The circular concludes as follows: "More than half of the 1,300,000 shares of Cumberland-Ely are owned by the Guggenheims and their associates. The rest of the stock is very widely distributed, the books of the company registering 1600 share holders. We believe that in the near future Nevada Consolidated and Cumberland-Ely will be joined in one great company. This coalition will insure Cumberland-Ely share holders an attractive proportion of the profits of its steam shovel neighbor." The italics are our own. The stockholders of the Nevada Consolidated are yet to be heard from.

New Mexico

GRANT COUNTY

Chino Copper Company—This is a new company organized by Hayden, Stone & Co. to operate the Santa Rita mine. Of the authorized issue of 700,000 shares, 375,000 shares are being delivered in exchange for an equal par value of the entire capital stock of the Santa Rita Mining Company. Of the balance of 325,000 shares, a portion is now being sold for cash at \$5 (par value) per share, and the balance is under option at the same price. Active operations at the property in the development of the porphyry deposits have already been begun under the direction of A. Chester Beatty, who is engineer for the new company. John M. Sully has been put in charge of the property. D. C. Jackling will be chairman of the board of directors.

SOCORRO COUNTY

Socorro Mines—The company has secured control of the Little Fannie, Champion and Consolidated groups at Mogollon. The mill at present is treating 60

tons per day with an extraction of 89 per cent. A new 150-ton mill is being built, also a 600-kw. hydroelectric plant.

Pennsylvania

ANTHRACITE COAL

Philadelphia & Reading Coal and Iron Company—The statement for April and the 10 months of the fiscal year from July 1 to April 30 is as follows:

	April.	Ten Mos.
Earnings.....	\$4,639,804	\$30,292,772
Expenses.....	4,376,821	28,609,376
Net earnings.....	\$ 257,983	\$1,682,797

For the 10 months there were decreases of \$2,568,799 in earnings; of \$1,990,903 in expenses, and of \$577,806 in net earnings.

Delaware, Lackawanna & Western—The old wooden breaker at the Taylor colliery, near Scranton, is to be replaced by a reinforced concrete structure. In this the company is following its recent policy of using concrete wherever possible. Wooden breakers are comparatively short-lived; but the most serious objection to them is their liability to take fire, involving not only the destruction of the building, but the loss of valuable machinery. The plans for the breaker have been drawn by Bradford Sampson, Lackawanna superintendent of construction.

BITUMINOUS COAL

Monongahela River Consolidated—The financial statement for the half-year ended April 30 gives the net earnings at \$978,511, a decrease of \$373,078 from last year. Charges were: Royalty, \$199,542; depreciation, \$212,098; taxes, insurance and interest, \$447,575; total, \$859,215. This left a surplus of \$119,296, which is a decrease of \$291,193 from last year.

South Dakota

LAWRENCE COUNTY

A severe flood has caused a suspension of most of the mines in the Bald Mountain district. Few of the mines were flooded, as electric power was available and in almost every case the pumps were kept going. Railroad connection with the mills, most of which are at a distance from the mines, has been broken. All those treating Bald Mountain ore have temporarily suspended.

Utah

BEAVER COUNTY

Cedar-Talisman—A large cave has been opened and on its floor is a layer of 3 or 4 ft. of lead carbonate ore with evidence of higher silver content than in the other ores of the mine. S. S. Pond, manager, Beaver, Utah.

JEAR COUNTY

Chief Consolidated—This company has purchased the Granite claim and one-half interest in the American Star and Blackbird claims. This new ground, together with the Little Chief holdings, gives the company a desirable territory in the Tin tie district.

Montana—Orders have been placed for buildings and equipment for this property. The purchase includes a 125-h.p. compressor, an 8x10 air hoisting engine capable of operating to a depth of 750 ft., power drills, and ventilating and lighting systems.

Iron Blossom—The management is opening an orebody in a drift from the south shaft that promises to become an important source of revenue. President Jesse Knight said: "We are drifting on a full face of ore which contains no lead, but of uniform content of silver and gold which makes it of shipping grade. We have followed a streak of copper ore to considerable depth in this shaft, and this leads me to believe that with depth we will find plenty of copper ore in this part of the property."

Tintie Standard—The big fissure which has just been crosscut on the 400-ft. level is proven to be 87 ft. wide. The grading for the headframe for the new shaft has been completed. The hoist is to have a capacity for sinking 1000 ft. E. J. Radatz, general manager, Eureka, Utah.

UTAH COUNTY

Mountain Dell—A streak of high-grade silver ore, described as "almost native," has been found in the raise which is being driven to connect the 800-ft. tunnel with the inclined shaft in American Fork cañon. The tunnel will be completed in 30 days and it is then expected to develop the high-grade streak. Considerable ore of shipping grade has been developed in the shaft. R. N. Baskin, general manager, University Club, Salt Lake City.

Burgess Consolidated—This property, immediately south of Miller hill, in American Fork cañon, will resume work.

Virginia

BUCKINGHAM COUNTY

Ferncliff Slate Company—This company, with office at Rochester, N. Y., proposes to develop slate properties at Arvoria; also proposes manufacturing structural and roofing slate, slate acid vats, slate insulators for electrical wires, etc. E. E. Crook is general manager.

Washington

JEFFERSON COUNTY

Construction on James A. Moore's steel plant at Irondale continues steadily.

KING COUNTY

Grand Ridge—C. J. Smith, A. S. Kerry and Andy Reynolds, of Seattle, have purchased the Grand Ridge coal properties at Issaquah under the name of the Central Coal Company, and will mine coal within 90 days from a portion of the 400 acres acquired.

West Virginia

MONONGALIA COUNTY

Frank Rook and associates, of Union-

town, Penn., have purchased 3000 acres of coal lands in Monongalia and Marion counties. It is proposed to construct 1000 ovens, to have a daily production of 2500 tons of coke. L. A. Phillips, of Grays Landing, Penn., is the engineer in charge of construction.

Philippine Islands

BENGUET

Benguet Consolidated Mining Company—The output for the month of March was 235 oz. gold.

CAMARINES

San Mauricio—The equipment has arrived and is now being installed. It is the largest shipment of mining machinery ever brought to the Philippines. It includes a complete mill of 20 stamps, concentrators, an electric-light plant complete and power machinery. President Heise states that the installation will be complete and the plant operating by the end of 1909.

PARACALE

Paracale Gold Dredging Company—This company reports 644 oz. gold saved in March from its dredging work in the Paracale river.

Canada

BRITISH COLUMBIA—QUEEN CHARLOTTE ISLANDS

Awaqa Ikeda & Co.—Ore shipments in May to the Tyee smelter at Ladysmith totaled about 1000 tons, making nearly 9500 tons since shipments were commenced. Output for April was 884 tons, averaging 7 per cent. copper and about \$3.50 per ton in gold and silver. Total footage in four tunnels driven is 1500 ft. Lowest tunnel is in 800 ft. in ore practically all the way. Recently a 6-ft. dike was encountered and after going through this the tunnel entered an orebody proved to be 26 ft. wide with a footwall not yet reached. The manager, A. Ikeda, of Vancouver, B. C., is arranging to install additional power equipment. Recent developments at this mine are regarded as the most important that have taken place since the commencement of mining operations on the islands about two years ago.

BRITISH COLUMBIA—VANCOUVER ISLAND

Tyee Copper Company—Of several properties the company is developing, results from one or two indicate early profitable production on a considerable scale. The smelter at Ladysmith had a full month's run in April with one furnace, smelting about 7000 tons of ore. Much work is being done at mines from which the smelter derives its ore supply, so that directly market values improve there will be ample ore to keep two furnaces going. The second furnace is being installed. W. H. Trewartha-James, of Victoria, B. C., general manager, W. J. Watson, smelter manager, and J. W. Bryant, mining en-

ginger, have returned from their recent trip to Queen Charlotte islands.

NOVA SCOTIA

Dominion Coal Company—The coal output for May was 306,888 tons, as against 335,829 tons for May, 1908. The total for the five months ended May 31 was 1,263,458 tons, as against 1,578,923 tons for the corresponding period last year.

Nova Scotia Steel and Coal Company—R. E. Chambers, the company's iron-ore expert, has gone to Newfoundland to arrange for a larger output this season from the ore deposits at Wabana. Contracts for 310,000 tons for shipment abroad have already been made, of which about 100,000 tons will go to Germany, 150,000 to the United States and 60,000 tons to Great Britain. Thomas Cantley, general manager, estimates the coal output of the season at 800,000 tons, the company having a present coal-producing capacity of about 1,000,000 tons yearly.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ended May 29, were as follows: Buffalo, 43,574 lb.; Crown Reserve, 161,680; Chambers-Ferland, 60,000; La Rose, 105,680; McKinley-Darragh, 46,780; Nipissing, 194,146; Nancy Helen, 43,400; O'Brien, 128,190; Right-of-Way, 81,228; Temiskaming, 59,000; Trethewey, 65,300; total, 1,078,978 pounds.

Beaver—A new powerhouse, 35x50 ft., is being erected. A headframe will be built over the main shafthouse. New machinery is on the ground for installation when the buildings are completed. The first shipment will shortly be made, 235 bags of high-grade ore being already sacked.

Crown Reserve—Six drills are working on development operations and two on stoping. From the drift under the lake at the 100-ft. level a crosscut has been finished for 530 ft., and from No. 1 vein a crosscut has been run 87 ft., and has penetrated a diabase formation.

Hargrave—The main shaft on the Jacobs vein is down 270 ft., and will be sunk 30 ft. further, when a crosscut will be made to intersect the vein at the 300-ft. level and a drift run to the Kerr lake line.

King Edward—A discovery has been made in drifting at the 80-ft. level of No. 5 vein where a vein was struck 11 in. wide, running over 3000 oz. silver to the ton. The wallrock also carries silver.

Little Nipissing—A 12 in. vein of calcite running about 3000 oz. to the ton in native silver was struck on June 1 on the Peterson lake leasehold of the Little Nipissing, on a raise between the 100- and 100 ft. levels.

Silver Leaf—The diabase formation will be explored in the expectation of finding Huronian underneath it. A shaft on the north end of the property is down 40 ft.,

and will be put down to 300 ft. with the object of reaching the Huronian. Forty men are at work trenching.

Cobalt Gem—A massive nugget 5 ft. 6 in. in length, 2 ft. 5 in. wide, and 16 in. thick, 75 per cent. pure silver and valued at \$16,000, has been found near the surface at the foot of a cliff 60 ft. high on this property. It will be forwarded to Philadelphia, the company being controlled by people in that city.

La Rose—This company has obtained permission from the Right-of-way to run a crosscut under the railway so that it can work its holdings on the town side of the track, which will be developed from the first level of the La Rose. The work on the crosscut has been begun.

ONTARIO—MONTREAL RIVER DISTRICT

Otis-Currie—Another shaft is being put down on the northeast corner of the property. At the depth of 6 ft. the vein shows about 7 in. of decomposed calcite, cobalt, galena and silver. At No. 1 shaft 71 ft. of sinking, 161 ft. of crosscutting and 133 ft. of drifting have been accomplished, and the vein continues to hold its value.

Mexico

CHIHUAHUA

Calabacillas—A 50-ton cyanide plant is being erected at this mine, not far from the Sinaloa and Durango State line. The plant is for handling the accumulated tailings, as well as a large tonnage of low-grade ore. The property is owned and operated by W. H. Brevoort, of New York and Paris. The mine is reached from Fuerte, Sinaloa.

Lluvia de Oro—Burt filters are being installed at the cyanide plant. The small plant has proven so successful that plans are being made for the early erection of a larger one. A small amount of bullion is being produced from working over the old tailings.

Tepoehique Gold and Silver Mining Company—The mine is situated in the vicinity of Barranca de Cobre and is preparing for the early resumption of work under the direction of Dr. C. F. V. Caracristi.

Moris Camp—A number of mining properties in this district have recently been purchased by Canadian capitalists, among whom is the owner of the O'Brien mine at Cobalt.

Santa Elena and Bert—J. D. McKenzie and J. D. Harbottle, of Chihuahua, have acquired these properties, owned by R. Anderson in the Terrazas district. Development work is under way and a good showing of ore has been found in a 120 ft. shaft.

Durango Mines Company—H. B. Pope and other Pittsburg people have recently made another payment of 25,000 pesos on this property in western Chihuahua. It is

reported that the reduction works, consisting of amalgamation and cyanidation plants will be placed in commission shortly.

International Gold Mines Company—A Kansas City concern, managed by J. W. Pender, will discontinue cyanidation and return to concentration of its ores. The property is west of Ocampo in El Socorro district.

American Smelting and Refining Company—Two additional furnaces are being added to the Chihuahua plant, making five in all. This will give the smelter a capacity of 750 tons per day.

MEXICO

Esperanza—Report for April: The mill operated 27 days, crushing 14,451 tons of ore. Estimated value of bullion produced, \$127,785; estimated value of concentrates, \$49,848; receipts from rents and other sources, \$748; total, \$178,381. Less all working expenses and treatment charges on concentrates shipped to smelters, \$112,258. Net proceeds, \$66,123.

Mexico Mines of El Oro—Report for April: The 40-stamp mill ran 24 days, crushing 7240 tons of ore. Estimated value, \$110,120; working expenses, \$38,750; development expenses, \$6800; net proceeds, \$64,570. In addition to this 23 tons of high-grade ore were shipped to smelters, yielding net proceeds of \$6750. Total profit for the month, \$71,320.

SONORA

El Tigre—The adjourned annual meeting of the stockholders was held recently at Douglas, Ariz. The capital stock was increased from \$500,000 to \$800,000. Seven directors only were elected to take the place of 13 which have heretofore served. The new directors are T. C. Fooy, C. S. Jones, John B. Seitz, W. A. Moses, John Kelley, E. J. Street, and C. M. Evans, all of Kansas City. Of the \$800,000 of new stock voted, \$1,000,000 is placed in the treasury for further improvement at the mines. Six million, three hundred and fifty thousand dollars was declared as stock dividends.

Greene-Cannara—The May output was 3,010,000 lb. of copper, containing 84,600 oz. of silver and 500 oz. gold. This is slightly less than the April production.

Africa

RHODESIA

The gold output in April is reported at 5,000 oz. fine, being 4870 oz. more than in March, and making a total for the four months ended April 30 of 195,301 oz. By values, the total production for the four months was \$3,915,550 in 1908, and \$4,000,407 in 1909; an increase of \$84,047, or 2.2 per cent.

Other production reported in April was 21,495 oz. silver, 4 tons copper, 82 tons lead, 1748 tons chrome ore and 28 tons asbestos. Coal production from the Warlike mines was 13,498 tons.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, June 9—Reports from the West continue to be encouraging. An increased business is being done in steam coal at nearly all the large centers. Mines are running on better time and making larger outputs, and there is decidedly a more hopeful feeling in the trade. Car supply throughout the West is generally good and coal is moved promptly.

In the East the bituminous trade is improving, though much more slowly than in Western territory. Still, there is an improvement and indications are that it will continue.

The anthracite trade is quiet and steady. Production has been cut down in April and during the present month, and in consequence accumulated stocks are being gradually worked off.

Lake Coal Trade—The question of rates to Lake Erie ports on coal for shipment to the Northwest is still unsettled. It is understood that the West Virginia operators will continue to fight against the proposed differential rates before the Interstate Commerce Commission and in the courts.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to May 29 short tons:

	1908.	1909.	Change.
Anthracite	2,278,735	2,198,843	D. 80,192
Bituminous	13,154,386	14,352,766	I. 1,198,430
Coke	2,818,885	4,065,142	I. 1,246,257
Total	18,251,956	20,616,751	I. 2,364,495

Increase for the week, 181,498 tons. Total increase this year to date was 13 per cent.

The coal mined by the Monongahela River Consolidated Coal and Coke Company for the six months of its fiscal year ended April 30 was 3,254,055 tons in 1907-8, and 2,860,134 in 1908-9; decrease, 384,921 tons, or 11.8 per cent.

Anthracite coal shipments in May were 5,063,873 long tons, being 827,303 tons less than in April, and 1,268,501 tons less than in March. For the five months ended May 31 the shipments were, in long tons:

	1908.	1909.	Change.
Reading	5,173,553	5,396,756	I. 223,203
Lehigh Valley	4,531,018	4,397,739	D. 133,279
N. J. Central	3,696,195	3,965,138	D. 244,067
Lackawanna	4,115,385	3,942,193	D. 1,73,142
Del. & Hudson	2,784,864	2,870,585	I. 85,721
Pennsylvania	2,619,655	2,566,269	D. 53,386
Erie	2,958,100	3,359,100	I. 400,910
N. Y., Ont. & West	1,151,717	1,148,083	D. 3,634
Total	26,903,927	27,046,763	I. 142,836

Three companies showed increases and

five decreases. The total gain this year was 0.3 per cent.

Coal tonnage originating on the Southern railway, three months ended March 31: Alabama district, 564,936; Tennessee district, 336,244; total, 901,280 short tons, an increase of 320,580 tons over last year.

New York

ANTHRACITE

June 9—The anthracite trade is quiet and steady. Sales are about as usual at this time of the year. The collieries are beginning to run on a little better time as the stocks are being worked off.

There is no change in prices which are for prepared sizes, \$4.45 for lump, and \$4.70 for egg, stove and chestnut, all f.o.b. New York harbor. For steam sizes current quotations are unchanged at \$3.10@3.25 for pea, \$2.35@2.50 for buckwheat, \$1.70@2 for rice or buckwheat No. 2, and \$1.25@1.50 for barley, f.o.b. New York harbor points.

BITUMINOUS

The Seaboard bituminous trade is beginning to wake up and show some activity after its long rest. Mills and factories which have been scraping the boards in their coal bins are feeling the necessity of putting in more stocks. It is noticeable that many of the orders now received come with the request to ship as soon as possible.

The far East is doing best in the trade. The Sound is rather quiet. In New York harbor business is slow and the harbor is coming to be looked on as a dumping ground for cheap coal. The lower grades are selling at \$2.40@2.50 per ton, f.o.b. shipping port, and better grades \$2.50@2.60 and upward. The harbor docks are generally clear and there is no demurrage coal on the market.

All-rail trade is still improving and has now reached a fair basis. Car supply is good, but transportation is rather slow, dropping a little behind the schedule in many cases.

In the Coastwise trade small vessels are rather scarce, but large boats are plenty, and in the whole it is a shipper's market for tonnage and freights are low. For large vessels from Philadelphia quotations are 75@80c to Lynn and Newburyport; 60@65c to Boston, Saco and Portland; 45@50c to Providence and the Sound. From New York rates are 60@65c. to points around Cape Cod.

There has been some inquiry for outside

coal for the West Indies, but sailing vessels are reluctant to take business at this time of the year, being afraid of bad weather and hurricanes.

Birmingham

June 7—The coal trade in Alabama is dragging along. There is not much being done at the mines. The coming convention of the United Mine Workers of America, Alabama district No. 20, to start on June 14, is to be watched closely by the operators in this section. Reports have it that the officials of the union have been making an effort to reorganize the men and bring about more trouble. From the headquarters of the operators it is learned that there will never be any more recognition of the union miners in this State, so far as the larger operators go.

Coke is in steady demand with the production being held up well. A Dempster, of Pittsburg, was re-elected president of the Corona Coal and Iron Company at a meeting held here last week. The Corona company has had a prosperous season, despite the dullness of the coal trade.

Chicago

June 7—Coal consumption is down to its normal summer level, to all appearances. There is a fair demand for fine steam coals; lump suffers from the drift of the market, the trade centering about Illinois and Indiana screenings. For steam lump and general domestic coals there is practically no market. Contract business has obtained most of the big consuming interests, at low figures. Run-of-mine is hard to sell.

Illinois and Indiana coals bring in car lots \$1.55@2.25 for lump or egg; \$1.65@1.75 for run-of-mine; \$1.35@1.65 for screenings.

Eastern coals are slack. Smokeless run-of-mine is in too large supply and sells for \$2.05@3.05, with lump at \$3.20@3.25. Hocking is still too abundant, bringing 10c, or 25c, under the \$3.15 list price. Youghiogheny continues even at \$3.15 for 34-in. coal and Pittsburg No. 8 is quiet at \$2.65 for 34-in. lump, the demand for both being light.

Anthracite sales are light, in both city and country.

Cleveland

June 8—Lake coal is moving more freely, the docks and yards being less crowded. The railroads, however, want

to see more improvement before they take coal for the Lake trade from the mines.

Local business shows improvement, and steam coal is being taken readily in quarters where buyers have been holding back. Slack is in best demand. No. 8 district brings \$1.05@2.05 for lump; \$1.70@1.80 for run-of-mine; \$1.40 for slack, all f.o.b., Cleveland. Middle district runs about 10c. under these prices.

Indianapolis

June 7—In a general way the coal situation presents additional favorable features, but there is still room for a larger advance both in output and price. There is less heard of empty coal cars on the sidings, of the timidity of buyers, of the strike on the Lakes. Blast furnaces and mills continue to increase operations and these are regarded as hopeful signs and Indiana mines are beginning to profit by the increasing consumption for these and other purposes. There were more mines in operation during the past week than since last March and more men were employed. Two or three mines resumed operation after months of idleness and work is progressing on several shifts in new territory.

Pittsburg

June 8—The heavy rains of last week brought a good stage in the rivers, and about 5,000,000 bu. of coal have gone down this week. The coal market remains rather quiet. Nominal prices are continued at \$1.10 to manufacturers and \$1.20 to retail dealers, for mine-run at mines, these prices being shaded 5 to 10c. per ton. Slack is quoted at 6c to 65 cents.

Connellsville Coke—The positive statement is made on behalf of the promoters of the Connellsville coke merger that the parties back of the movement are interested in the consumption of coke and have business reasons for desiring to acquire the properties; but no direct statement can yet be obtained as to who are back of the purchase. The appraisers are at work. There are four options involving prices of \$5000 an acre or higher, but these cover a relatively small acreage, and the promoters expect to be able to scale them down 20 per cent. The remainder of the options on Connellsville coal are claimed to run from \$2200 to \$2700 an acre. There are about 90,000 acres in the Connellsville region, of which the United States Steel Corporation controls 10,000 acres. Of the remaining 30,000 acres it is expected 20,000 acres will be purchased, while about 15,000 acres of Greene county coal will be taken, making 35,000 acres altogether to go into the merger, which will be capitalized at \$60,000,000. The stock has all been underwritten, and while some of the sellers will be urged to take some stock in the new

company it is represented that it is desired to have them in for the purpose of having practical coke operators interested.

The report is confirmed that the three-year contract between the Jones & Laughlin Steel Company and the Thompson-Connellsville Coke Company was at \$2 per ton at ovens. A steel company has just taken 50,000 tons of coke for second half, at \$1.60 at ovens, this being to supplement its own production. The market for Connellsville furnace coke remains at \$1.50@1.60 for prompt and \$1.60@1.80 for contract, according to grade. Foundry coke is \$1.80@2 for prompt and \$1.90@2.25 for contract, depending on grade.

The *Courier* reports production in the Connellsville regions for the week ended May 29 at 284,866 tons, a gain of 6000 tons. Shipments are: 3637 cars to Pittsburg district; 5595 cars to points west of Pittsburg; 739 cars to points east of Connellsville; total of 9371 cars, or 500 more than the preceding week.

Foreign Coal Trade

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on May 29: Best Welsh steam, \$4.02; seconds, \$3.84; thirds, \$3.60; dry coals, \$3.84; best Monmouthshire, \$3.48; seconds, \$3.36; best small steam, \$2.64; seconds, \$2.46. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, June 9—The iron and steel markets continue generally active. New business just now is coming in perhaps in rather less volume than in May, but still in sufficient quantity to keep the mills active with fair prospects of remaining so for some time to come.

In pig iron, foundries generally are placing orders quite freely for the third quarter, and to some extent for the fourth quarter also. Buyers seem to be no longer feeling their way, but are ready to take on considerable stocks, evidently believing that they will be able to use them to advantage. Furnaces generally are firmer in their views and are asking at least 25c. more per ton than last month, generally with an advance of 50c. for fourth-quarter deliveries. Basic iron has been in strong demand and large sales have been made. Parallel with this is a call for heavy steel melting scrap, which is getting to be rather scarce and bringing good prices.

In finished material, structural steel continues in demand; while few large contracts have been placed, there have been many small orders making up a good volume of business. Bars have also been selling freely. In plates demand has improved owing to the placing in the East of several contracts for new ships for the coasting trade. The shipyard activity on

the Atlantic coast promises to be greater during the coming season than for some years past.

Railroads have been ordering freely for new equipment. A recent estimate is that 950 locomotives and 21,500 cars have been ordered in the five months ending May 31. Rail orders are still light so far as standard sections are concerned, but light rails have sold quite freely and there is a good deal of trolley-rail business in sight. Some good contracts have already been placed.

Tinplate Wages—It is stated that the American Sheet and Tin Plate Company will make no agreement with the Amalgamated Association this year, but will run all its plants on the open-shop plan after the present agreement with the association expires.

Baltimore

June 7—Exports for the week included 3,271,760 lb. steel billets to Liverpool; 1396 tons steel rails to Bahia Blanca and 5137 tons to Guaymas, Mexico; 840,223 lb. pipe to Panama; 81,800 lb. tin scrap to Antwerp. Imports included 700 tons manganese ore from Germany and 350 tons from Cuba; 11,350 tons iron ore from Cuba; 4239 tons cupreous pyrites from Spain.

Birmingham

June 7—The month of June started off well with the Southern pig-iron manufacturers. There has been a steady inquiry for iron and the sales so far this month more than equal the make. No. 2 foundry is being held for \$11.50 per ton, minimum, while \$12 is being asked for third-quarter delivery and some sales being made. Three furnaces went out of blast during the past fortnight and one more will be cold within a few days. However, every preparation has been made for a resumption at two furnaces and two others will soon be in condition to resume operation. The home consumption continues to show improvement, the cast-iron pipe makers having large orders on hand and the machine shops and foundries receiving business right along. During the month of May the iron producers in Alabama sold more than their make. The make so far this month has been covered. The Ensley steel plant is still idle.

Chicago

June 7—Conditions in the iron and steel market remain indicative of a bright future but with business in pig iron still sluggish. The ordinary consumer is not yet buying for the future; he is awaiting developments of tariff, general market conditions and a host of other things. His purchases are small and for the next three months, as a rule. When he contracts into the last quarter it is also for small amounts. The large consumer—he who

buy in lots of 1000 tons or more—is equally cautious. Both sides—the selling and the buying—are awaiting developments.

Southern iron hovers about \$11.50 Birmingham (\$15.85 Chicago). Sales probably have been made—those most favorable to the seller—at 50c. below this price. On the other hand, some have been made at \$12 Birmingham. What price a large order would bring is questionable. Northern iron holds to \$16.50 base price for No. 2, with furnaces reported close to demands and producers still conservative. Lake Superior charcoal, with a tight market, brings \$19.50.

Iron and steel products continue active. Coke finds a steady market at \$4.70 (or \$2.05 at the ovens) and the supply well regulated to the demand.

Cleveland

June 8—There has been more buying of iron ore, now that the price is established. The quotations are \$4.50 for Old Range and \$4.25 for Mesabi bessemer; \$3.70 for Old Range and \$3.50 for Mesabi non-bessemer, all f.o.b. Lake Erie ports. Guarantees are 55 per cent. iron on bessemer and 51.5 on non-bessemer ores. The strike is making some trouble still, but there are plenty of vessels moving.

Pig Iron—A good business is being done, with prices 25c. higher, the base being \$15.25@15.50 for No. 2 foundry.

Finished Material—New sales are a little slower, but deliveries on contracts are being urged. Plates are more in request, but business in bars is lively, and structural steel orders are still coming to the mills.

Philadelphia

June 9—The sum total of sales in eastern Pennsylvania for the past week falls below that of some previous like periods. The lack in sales was made up in inquiries. Prices quoted show a hardening, especially for basic, which promises to be called for in considerable quantities owing to recent favorable developments in the steel industry. Inquiries for low grades of pig iron are under consideration by one or two furnace companies. Electrical equipment manufacturers are in the market for special brands, the stocks of which are practically exhausted. The most significant feature of the situation is the practical absence of stocks of desirable irons. Forge iron continues to drag. Foundry is strong even in the absence of large sales. No. 2X is quoted at \$16.50, forge, \$15; basic, \$15.50, with an upward tendency.

Steel Billets—Billets are decidedly stronger under heavy buying. Negotiations now in progress for large quantities.

Bars—There is a larger demand for

common iron especially. Mill owners are snatching up all the business they can get and are quoting 1.30c. delivered.

Sheets—Still further improvement is noticed in mill orders. The industry as a whole is gaining ground, though full capacity is not reported.

Pipes and Tubes—Liberal buying is in progress and prices are hardening.

Plates—A marked improvement in demand was developed within a few days. It is said an advance in early-delivery plates will be made.

Structural Material—A large volume of business has been placed at the mills and the daily receipt of inquiries is encouraging manufacturers. Prices are not advanced but a change is looked for in quotations.

Scrap—Heavy steel scrap is pretty well cleaned up and yardmen are on the war-path trying to fill new orders for steel mills. Light scrap is dull, except No. 1 yard. The large dealers are scurrying after stock and stronger prices will be the outcome.

Pittsburg

June 8—The iron and steel trade is in a healthy and prosperous condition. While the full capacity is not engaged, production is at a higher rate than at any time since October, 1907. Outside of railroad material, the shipments of the mills are fully up to the rate prevailing before the panic, and in some cases at a greater rate.

Production of pig iron has shown a steady gain since about the middle of April, but the gain is altogether by the steel-works furnaces, the merchant furnaces not gaining any, but improving their position by ceasing the accumulation of stocks. Production of steel has shown a material increase. Many of the works are operating at absolutely full capacity.

Prices of finished steel products are substantially unchanged. There is a possibility of an early advance in wire products, possibly of \$2 a ton, while a similar advance in merchant pipe about July 1 is not altogether improbable.

Pig Iron—The tone of the local market is still stronger, and there have been fairly large sales in basic, with moderate sales in bessemer, while foundry and forge grades have been relatively quiet. Bessemer is held at a minimum of \$15. Valley, for prompt delivery, while most sellers are quoting \$15.25 for extended delivery, and sales have been made at this price. The minimum of the market on recent sales was \$14.50. Valley, this price being done both on prompt and on third-quarter delivery. Sales of basic aggregate for the last 10,000 tons have been made at \$14.25, \$14.35 and \$14.50. Valley, the market showing a sharply advancing tendency, and the present position being that nothing below \$14.50 Valley can be done, some fur-

naces quoting \$14.75 and some as high as \$15. The latter have practically withdrawn from the market for the present. The bessemer and basic averages, compiled from actual sales, have been as follows, Valley furnace: January, \$16.44 and \$15.50; February, \$15.88 and \$15.10; March, \$15.44 and \$14.94; April, \$14.90 and \$14.15; May, \$14.58 and \$14.12. The May average on bessemer corresponds with the low point of last year, made in October. April and May made new low prices on basic.

Steel—The several sales of sheet-bars made lately at \$24@25, delivered, for both prompt and second-half delivery, have attracted considerable attention, the official market being \$25.50. It is evident that the outside steel mills are willing to support the independent sheet mills in their contest for business with the leading interest. Billets remain firm at \$23, Pittsburg. The regular market on plates remains at 1.3c., especially attractive business being sometimes taken at 1.25 cents.

Sheets—Shading continues in sheets. The regular market is 2.20c. on black and 3.20c. on galvanized, 28 gage, Pittsburg, but these prices are sometimes shaded \$1 a ton. Corrugated roofing is nominally \$1.55 for painted and \$2.80 for galvanized, per square, but these prices are shaded \$2 a ton.

Ferromanganese—The market remains weak, \$40.50 to \$41, Baltimore, being quoted, equal to \$42.45 to \$42.95, Pittsburg.

Foreign Iron

Canadian Steel—The production of steel and of finished iron and steel in Canada for two years past was, in long tons:

	1907.	1908.	Changes.
Steel Ingots.....	646,754	509,957	D. 136,797
Finished Material:			
Wrought iron.....	81,093	65,505	D. 15,588
Steel.....	519,086	431,012	D. 88,074
Total.....	600,179	496,517	D. 103,662

Of the steel made in 1908 there was 108,433 tons bessemer and 401,119 tons open-hearth steel. The ingots included 99,57 tons direct castings. The largest item of finished material was 268,602 tons rails.

German Iron and Iron-ore Trade—Exports and imports of iron and steel, and of ores, in Germany, three months ended March 31, metric tons:

	Exports.	Imports.	Excess.
Pig iron.....	81,210	26,663	Exp. 54,547
Pig, 1908.....	66,221	60,983	Exp. 5,238
Other iron and steel.....	824,229	64,220	Exp. 760,009
Other iron, '08.....	807,880	78,474	Exp. 729,406
Iron ore, 1908.....	641,784	1,764,323	Imp. 1,122,539
Iron ore, '08.....	921,085	1,348,163	Imp. 427,078

Manganese ore, '08.....	440	91,735	Imp. 91,295
Slag and slag products, 1908.....	16,475	99,442	Imp. 82,967
Slag, 1908.....	16,373	118,278	Imp. 101,905

Iron ore includes pyrites residues, under and similar material

Metal Markets

New York, June 9.—The metal markets continue to show some improvement in demand and prices; also some speculative activity, especially in copper.

Gold, Silver and Platinum*

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
April 1909....	\$ 3,349,107	\$ 6,337,994	Exp. \$ 2,988,887
" 1908....	2,641,197	14,476,341	Exp. 11,915,144
Year 1909....	44,516,626	15,607,392	Exp. 28,909,244
" 1908....	18,336,344	19,857,221	Imp. 1,621,877
Silver:			
April 1909....	4,962,251	4,073,504	Exp. 878,747
" 1908....	4,462,554	3,467,926	" 994,638
Year 1909....	10,426,181	14,526,722	" 4,099,459
" 1908....	17,048,851	14,286,560	" 2,762,290

*Exports from the port of New York, week ended June 5: Gold, \$2,120,440, chiefly to Paris and Buenos Aires; silver, \$916,507, chiefly to London. Imports: Gold, \$128,426; silver, \$214,878, both principally from the West Indies and South America.

Gold—The demand for gold on the open market in London was not active and the Bank of England took most of the metal arriving.

Platinum—The market is rather weak and lower prices are not unexpected. Present quotations are \$22.50@23 per oz. for refined platinum, \$25 for hard metal and \$18@20 for good scrap.

Our special correspondent writes from St. Petersburg, Russia, under date of May 27, that the markets are a little better, and the demand sensibly increases. Recently an offer to buy 20 poods of platinum at 18,000 rubles per pood was refused here by the Platinum Company, one of the great producers. Generally prices remain unchanged and the crude metal, 83 per cent., is quoted at Ekaterinburg 4.50 @5 rubles per zolotnik; in St. Petersburg, 18,000@19,000 rubles per pood—equal to an average of \$17.86 and \$18.13 per oz., respectively. These prices are nominal and subject to negotiation.

Silver—The market has settled into very narrow channels. Absorption of silver continues, but there does not seem to be much prospect of a rise of any material consequence soon.

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—An outburst of speculative buying in all the European markets helped to carry the market forward further during the week. The business placed by consumers was of relatively small proportions. Toward the end of the week there was a realization of speculative holdings on a large scale, which tended to discourage new buying from that quarter, and the market closes barely steady at 13½@13¾c. for Lake copper; 13½@13¾c. for electrolytic in ingots, cakes and wirebars; 13½@13¾ for casting copper. The average of the week for casting copper has been 13½@13¾ cents.

Copper sheets are 17c. base for large lots. Full extras are charged, and higher prices for smaller quantities. Copper wire has been again advanced ¼c. to 15c. base, carload lots at mill.

The standard market in London, in which speculative activity centered, had advanced by Monday morning to the highest prices reached on this movement, and closing quotations of the first call on that day were cabled at £61 12s. 6d. for spot and £62 10s. for three months. Ever since there have been heavy realizing sales, which brought about a decline to £60 7s. 6d. for spot and £61 3s. for three months in the closing market of Wednesday.

For refined and manufactured sorts we quote: English tough, £65; best selected, £64@65; strong sheets, £70@78.

Tin—In sympathy with the advance in copper, the London market for tin has shown substantial strength throughout the week under review. Transactions increased considerably in volume on Wednesday, and reports are current that the bull party is engineering an advance. The market closes firm at £134 for spot and £135 7½. 6d. for three months.

The domestic market has been dull, the only exception being on Tuesday when some spot material was thrown on the market at somewhat below import prices. Future deliveries, however, were held at a premium, and the market closes at about 29½ cents.

Lead—The market is unchanged at 4.25 @4.30c. St. Louis, and 4.35c. New York.

The John Wahl Commission Company telegraphs us from St. Louis, under date of June 9, that lead is strong at the latest advance, and is salable at 4.32½@4.35c. for Missouri brands.

The London market has been holding its own, and closes steady at £13 3s. 9d. for Spanish and £13 6s. 3d. for English.

Spelter—In spite of the higher prices which have ruled of late, the production of this metal has not increased and it is generally recognized that the current output is not equal to the demand. Stocks are decreasing steadily on the one hand, while the consumption is expanding. During the week, heavy orders were again placed, particularly by the galvanizing industry, and the market advanced from day to day reaching at the close 5.20@5.25c. St. Louis, 5.35@5.40c. New York.

The John Wahl Commission Company telegraphs us from St. Louis, under date of June 9, that spelter is firm and active. The latest sales are on a basis of 5.30@5.32½ cents.

New York quotations for spelter June 3 were 5.27½@5.30c.; June 4, 5.30@5.32½c.; June 5, 5.32½@5.35c.; June 7, 5.35@5.37½c.; June 8 and 9, 5.35@5.40 cents.

The London market is unchanged at £22 2s. 6d. for good ordinaries, £22 7s. 6d. for specials.

Base price of sheet zinc is 6¼c. per lb., f.o.b. La Salle-Peru, less 8 per cent. discount.

Other Metals

Antimony—Business is waiting for some decision on the tariff. In the absence of sales quotations are nominally unchanged at 8¼c. per lb. for Cookson's; 7½c. for U. S.; 7½@7¾c. for outside brands.

Aluminum—Prices remain at 22@24c. base for No. 1 ingots; 31@32c. base for wire; 33@34c. base for sheets. Business is not especially active.

Cadmium—Current quotations 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Paul Speier writes us from Breslau, Germany, under date of May 29, that the price of cadmium, which in 1907 was 1500 marks per 100 kg., fell in 1908 to 575 marks. This year there has been a further drop, prices for metal guaranteed 92.5 per cent. being 450@475 marks per 100 lb.—average, 50c. per lb. These are the lowest prices ever made

Quicksilver—New York prices are still unchanged at \$44.50 per flask of 75 lb. Sales have been light. San Francisco quotations are \$44 for domestic orders and \$42 for export. The London quotation is £8 7s. 6d. per flask, but as low as £8 2s. 6d. is named by second hands.

Nickel—Large lots, contract business, 40@50c. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Magnesium—Quotations for this metal are \$1.25 per lb. New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

German Metal Imports and Exports

Imports and exports of metals—other than iron—in Germany, quarter ended March 31, in metric tons:

	Imports.	Exports.	Excess.
Copper.....	39,131	15,598	Imp. 23,533
Copper, 1908.....	48,773	18,516	Imp. 30,258
Tin.....	3,301	1,610	Imp. 1,691

Nickel ore, '08.....	1,038	163	Imp. 875
Miscellaneous.....	1,470	109	Imp. 1,361
Mis., 1908.....	1,470	109	Imp. 1,361

Imports of chrome ore was 6474 tons, an increase of 4097 tons. Imports of pyrites were 143,357 tons in 1908, and 108,123 tons in 1909; exports 3924 and 2306 tons for the respective years. Miscellaneous ores include uranium, molybdenum, tungsten and other minor metals, with some mixed or complex ores.

Zinc and Lead Ore Markets

Joplin, Mo., June 5—The highest price paid was \$46 per ton, the assay base price ranged from \$43.50 down to \$42 base for heads and as low as \$40 base for slimes of zinc sulphide. The average price, all grades, was \$39.56. An effort early in the week to lower the level of prices was met by an almost unanimous refusal to sell, and on Thursday the market was restored to a level of the previous week; for the higher base, while the low base was advanced. The highest price paid for lead was \$60 per ton for 250 tons. As much more was sold at \$59, but the bulk of the

shipment was at \$58 per ton, with a considerable tonnage of ore off grade selling at a price which lowered the average to \$57.20, all grades.

Year to June 5.....	61,280,860	2,316,480	4,145,500

In addition to the above there was shipped to the American Zinc Ore Separating Company—from Platteville 216,000 lb.; Linden 50,070 lb.; Rewey, 59,000 lb.—125,070 lb. and to the Joplin Separator Works, 153,000 lb. zinc concentrates.

There was shipped last week, not then reported, from Highland 192,400 lb.; from Linden, 125,490 lb.; from Harker, 228,600 lb.; from Highland, 106,080 lb.; from Harker, 51,600 lb. lead ore.

Chemicals

New York, June 9—The principal activity is in contract deliveries. New orders are not coming in freely in most lines.

Copper Sulphate—Quotations remain at \$4.25 per 100 lb. in carload lots and \$4.50 per 100 lb. in smaller parcels. Business is quiet.

Arsenic—A fair amount of trading has been recorded. Prices are 2½@3c. per lb. for white arsenic.

Nitrate of Soda—The market is firm and sales good at last quoted prices, 2.25c. for spot nitrate and 2.1½c. for futures.

Mining Stocks

New York, June 9—The general stock market has faltered a little in its upward course. The bull movement which was started last week has been interrupted by one or two days of reaction and in some stocks there was a good deal of liquidation and consequent lower prices. The indications are that this is only a temporary condition, and most operators are looking for higher prices again. At the close the tendency is rather uncertain.

A good deal of interest is being shown in the arrangement for listing Steel Corporation stocks on the Paris Bourse. There is much curiosity to see how this attempt to give Steel securities a wider market will succeed. On this market they remain very strong.

There was one sale of Homestake of South Dakota during the week at \$91.50 per share for a small lot.

On the Curb the copper stocks were active but rather irregular in price. The Curb had its reaction also which carried down some shares, but left others untouched. The Nevada gold stocks are holding their own better. Cobalt stocks are in demand, and interest in them is being worked up in every possible way.

Boston, June 8—Outside of a sensational drop in Mass mining stock there have been no alarming developments in the local market. This stock was bulled to \$18.25 a week ago and had a rapid decline to \$8.50, the interval between these extreme prices being only three days. The finding of a new orebody some months ago was the cause for bulling the stock from around \$6 to the high price mentioned above. A mill run of about 600 lb. of rock from this new vein yielded considerably less than 1 per cent. copper, which was disappointing and the cause of the subsequent break. A rally to \$10 followed, but the price today was close to \$9.

Sentiment on copper shares is very optimistic, and today's market showed a material broadening tendency.

North Butte had a \$5 bulge today to above \$61.75. The bear selling seems to

be at an end. Copper Range displayed good rallying power, advancing to above \$83. Old Dominion rose \$2 to \$57.50, and Shannon touched \$17. Stockholders of this company have authorized the directors to guarantee the principal and interest on \$500,000 in 6-per cent. 10-year bonds to be issued by the Shannon-Arizona railway, convertible into Shannon Copper stock at \$20 per share. They have also authorized an increase of 30,000 shares of Shannon stock for the exchange. These bonds are being offered to Shannon stockholders, of record June 15, in the proportion of one \$1000 bond for 500 shares of stock. Shannon rights sold up to 30c. today.

North Lake mining attracted considerable attention by its \$1.75 advance to \$10.75. Advices state that the drill at No. 3 hole encountered copper.

The declaration of the regular quarterly dividend of 50c. by the Utah Consolidated had a stimulating effect, causing the stock to stiffen to \$44.

Curb trading has been in the better class of stocks. Outside of sharp breaks in Davis-Daly and Ohio Copper there were no particular features.

Salt Lake City, June 24—During the month of May, 3,045,395 shares of stock sold for \$2,123,162 on the Salt Lake Mining and Stock Exchange. The market was a broad one and holders of stock had no trouble in making sales. The feature of the month's trading was a slump in Iron Blossom, which declined after many heavy sales.

NO. 25.

The Lorraine Deposits of Oolitic Iron Ore

A District with Extensive Reserves of Nearly Self-fluxing Ores, Admirably Adapted to the Basic Steel Processes by their Phosphorus Content

B Y T O N Y C A L L O T *

The iron mines of Lorraine are of great interest to the miner, the metallurgist and the economist. The miner will consider the importance of the deposits, the various methods of working the seams and the special difficulties that were encountered in shaft sinking. The metallurgist will recognize the importance of finding an ore directly suitable to the Thomas basic converter process, and the economist will appreciate the many problems that may arise from an iron field spreading over four different European countries and constituting the largest iron deposit in the world. The reserve is estimated at 4,000,000,000 metric tons.

their enormous tonnage are situated close to existing railway systems, not far from the German collieries and in a rich and well developed part of the world. In addition coal seams have been discovered recently at deep levels under the iron seams, and although they present great difficulties in working they may be considered of importance for the future.

As will be seen on the accompanying map, which shows only the more important portion of the iron field, the mines extend over territory mainly in French and German Lorraine, and over a limited portion of Luxemburg and Belgium. These deposits have been known for more than

output which in 1906 was about 27,000,000 tons. The relative importance of this deposit in the three leading countries is shown by the following statement of their reserves: Luxemburg, 300,000,000 tons from an area of 3600 hectares; Germany, 1,100,000,000 tons from an area of 43,000 hectares; France, 2,500,000,000 tons from an area of 43,186 hectares; giving a grand total of about 4,000,000,000 tons and an area of 89,786 hectares. Mr. Bailly, engineer of the French government, has estimated the probable development of the mines in these three countries and has graphically represented these reserves in an accompanying diagram.

GENERAL VIEW OF SURFACE EQUIPMENT AT THE MOUTIERS IRON MINE—BRIEY DISTRICT

To realize the importance of this iron field the reserves of the most important fields of the world must be quoted; they are as follows, according to various authors: Great Lakes (U. S. A.), 1,000,000,000 metric tons; Bilbao (Spain), 25,000,000; Sweden, 800,000,000; Ural (Russia), 800,000,000.

The well known Bilbao district never contained more than 100,000,000 tons. The new Ouenza mines (Algeria) that are to be worked soon are situated in a wild country; they will not yield more than 60,000,000 tons and will necessitate the construction of a special railway 140 km long, while the mines of Lorraine with

a century and until the war of 1870-71 belonged almost entirely to France. When the new boundary between France and Germany was marked on the ground, the German representatives were accompanied by the chief engineer of mines of their Government with a view of getting most of the mines known at that time.

INFLUENCE OF BASIC STEEL PROCESSES

Since 1871 the development of the iron mines has been considerable, particularly since the invention of the Thomas basic converter process in 1880 which made possible the treatment of the phosphoric ores known in Lorraine as *minettes*. The discovery of the deep levels of the Briey district has given a new impulse to the

The output is increasing every year in Germany and France and remains stationary in Luxemburg. The official statistics give Luxemburg an annual production of 6,000,000 tons; Germany's production in 1906 was 14,000,000 tons as against 7,500,000 in 1900. In 1900, France mined in this field only 4,500,000 tons, 7,800,000 in 1906 and 8,738,000 tons in 1907. Belgium produces only 70,000 tons yearly. Though the French output is the lowest, its reserves are probably the largest. This is due to the fact that the ferruginous deposit outcrops mainly in Luxemburg and Germany. In France the principal mines are "deep levels" which were only opened after carefully prospecting the Briey district during the years 1894 to 1899. How-

*Mining engineer, 160 Boulevard Malesherbes, Paris, France.

ever, from a French point of view it is notable that these mines take every year a larger place in the general output of iron ores. The Lorraine production now constitutes over 85 per cent. of the French iron-ore output and about 70 per cent. of the total production of pig iron.

DESCRIPTION OF THE DEPOSITS

As will be seen from the accompanying map, these deposits are located in the eastern part of France and western part of Germany. The country is hilly and consists of uplands divided by the valleys of several tributaries of the Meuse and Moselle rivers. They are in the "Basin of Paris," a large basin where the ancient seas have deposited sediments from the lowest Jurassic up to the upper Tertiary, all the ore seams being inclined toward the center of the basin.

The iron seams of Lorraine are at the upper level of the Toarcian and rest upon green pyritic marls and sandstone. Just above them are micaceous marls belonging to the Bajocian. The ferruginous deposits comprise a number of seams separated by more or less sterile marls or limestones. A drilling made at Villeroy (France) encountered these various seams and their analysis and thickness are given in the accompanying table.

DRILL CORE OF LORRAINE IRON DEPOSIT.

Description of the Seam.	Thickness in Meters.	Fe Per Cent.	CaO Per Cent.	SiO ₂ Per Cent.
Micaceous marls.	18.80	5.72	3.65	58.8
Poor limestone.	2.10	13.78	33.30	11.02
Ferruginous limestone (I).	2.00	24.24	16.84	14.21
Poor limestone. (II).	4.00	10.60	34.35	11.97
Poor red seam. (III).	2.75	18.70	28.73	15.50
Ferruginous gray and blue marl. (IV).	4.60	19.28	18.01	26.18
Yellow seam. (V).	1.20	33.69	14.31	7.29
Gray seam. (VI).	4.20	39.10	6.95	6.97
Brown silicious seam. (VII).	1.95	30.86	8.78	20.27
Ferruginous marl. (VIII).	8.25	11.10	12.75	27.58
Black vein. (IX).	1.15	32.58	12.47	4.95
Gray vein. (X).	3.62	23.51	5.64	29.34
Upper Lias sandstone (wall of the deposit).	0.40	11.84	9.37	48.92

The percentages and thicknesses of the seams vary greatly with the locality where the sample is taken and the line of separation of the seams is not always precise. In the Briey district, the miners call the veins I and II the upper level, veins III and IV the middle level, and the veins V, VI and VII the lower level. It is difficult to say *a priori* which seam will be payable as this depends chiefly on the local conditions and management. Usually not more than three veins are worked at the same time in the deep mines. For example, at Micheville the output is about 1000 tons per day, divided as follows: Ferruginous limestone (I), 650; red seam (II), 250; gray seam (IV), 100 tons. The ore from vein I averages 29 per cent. iron; from vein II, 38 per cent., and 40 per cent. in the gray seam.

In general the total thickness of the whole of the ferruginous deposit varies from 25 to 50 m., being smaller near the ends of the formation. For example, the thickness never exceeds 10 m. at the south, near Nancy, while the exploitable portion is about 50 per cent. in quarries, and decreases to 15 and even 10 per cent. in the deep mines. The average inclina-

THE BASIN OF BRIEY

The basin of Briey in France is of much importance to the iron works of the region and is the continuation of all the above basins under 100 to 200 m. of barren limestone. The researches in this basin were the result of the absence of lime in the silicious and poor iron ores of Longwy. The numerous companies which

SKETCH MAP OF THE LORRAINE IRON FIELD

tion of the seams is 1 to 2 per cent. toward the west. They outcrop all along the Jurassic hills of Lorraine, and are divided by the geologists into several basins, as follows: In France, in the basins of Nancy and Longwy; in Luxemburg, in the basins of Differdange and Esch-Rumelange; in Germany, in the basin of Moyeuvre-Illyange.

own iron and steel works in French Lorraine close to the German boundary, knew there were many calcareous iron ores mined in Germany, and started drilling in the early '80s. They found the seams at varying depths and requested concessions, the first of which was granted in August, 1884.

The difficulties of sinking the shafts

were great as large quantities of water were encountered, as much as 3 cu.m. per min. having to be pumped out. These difficulties joined with an industrial crisis after 1888 caused the abandoning of all the attempts to sink shafts. Three years later de Wendel & Co. resumed their work at Joeuf, and after a second unsuccessful attempt, succeeded in 1896 in sinking the first shaft of the region to a depth of 70 m. The first ore was hoisted in 1898. The other companies profited by this first success and the Société des Hauts Fourneaux, Forges et Aciéries de Pont à Mousson in 1897 started a shaft by freezing the ground and completed it with success in 1900. This was the only shaft sunk by the Poetsch freezing process in this region. The other companies were able to sink their shafts by pumping out about 3 cu.m. per min. Some companies met with still larger quantities of water. For example, at Moyeuve (German Lorraine) they pumped out an average of 12 cu.m. of water per min., the maximum being 30 cu.m. per min. in the wet season. All these shafts range between 100 and 250 m. deep.

The basin of Briey has been divided by geologists into four subsidiary basins, this separation being based on the numerous faultings which are encountered and which are of considerable importance from two points of view: that of geology, and of

posing into a pulverulent oxide of iron. Thus the iron oxide would be situated along these faults and close to them. The accompanying section through Luxemburg will show the importance of these faultings and explain why the ferruginous seams are in the same locality sometimes worked by quarries, by galleries on hill-sides, and by shafts.

HYDROLOGY OF LORRAINE

The hydrology of Lorraine is of im-

portance to the mineowners by reason of the quantities of water that are met with both in sinking shafts and in developing the mines. The presence of water is due to three causes: (1) The rivers, mainly to 18; MgO, 1.22; H₂SO₄, 0.22 (S = 0.08). Phosphorus is present as phosphate of lime and phosphate of iron. It is in close relation with the iron and its percentage varies with that of iron in the oolitic ore.

GRAPHICAL REPRESENTATION OF THE ORE RESERVES IN THE LORRAINE FIELD

portance to the mineowners by reason of the quantities of water that are met with both in sinking shafts and in developing the mines. The presence of water is due to three causes: (1) The rivers, mainly

to 18; MgO, 1.22; H₂SO₄, 0.22 (S = 0.08). Phosphorus is present as phosphate of lime and phosphate of iron. It is in close relation with the iron and its percentage varies with that of iron in the oolitic ore.

CROSS SECTION THROUGH LUXEMBURG—NORTHEASTERN SECTION OF THE LORRAINE IRON FIELD

hydrology. The main faults are shown on the accompanying map, as well as the outcrop of the ferruginous deposits, and in dotted lines the contours of the gray seam. These faults are the boundaries of the basins, which are named Bassin de l'Orne, de Moutiers-Avril, d'Aumetz-Tucquegnieux and de Landres.

The geologists who have studied the basin of Briey attach much importance to these faults in explaining some of the peculiarities of the deposits, and especially the fact that the veins are richer along the valleys than under the uplands. It should be noticed that the main faults are almost parallel to the valleys of the region. There are, however, two systems of faults at right angles, the main one being southwest-northeast and the others southeast-northwest. As the zones of richness of the ore have the same setting, Mr. Villain, mining engineer of the French government, presented in 1902 a theory in which he considers these faults as feeders through which the thermal waters, saturated with carbonate of iron, welled up under the Toarcian, the carbonate decom-

posing into a pulverulent oxide of iron. Thus the iron oxide would be situated along these faults and close to them. The accompanying section through Luxemburg will show the importance of these faultings and explain why the ferruginous seams are in the same locality sometimes worked by quarries, by galleries on hill-sides, and by shafts.

The varying conditions throughout the Basin of Briey, due to the various inclinations of the faults and positions of the rivers, cause great differences in the quantities of water that are to be pumped out in the four secondary basins. The average quantities of water in cubic meters per minute that are encountered in sinking shafts in the various basins are: Orne, 2.75; Aumetz-Tucquegnieux, 6.66; Landres, 1.75; Moutiers-Avril, 1.33. In development work less water is encountered; the Orne basin is an exception, however, the average flow there being about 475 cu.m. per minute.

THE PHOSPHORUS CONTENT

The main feature of this ore is the constant presence of phosphorus. The ore

However, in the poor ores its proportion increases, owing to a larger quantity of phosphate of lime. In the gray seam, which is the favored one in Lorraine, the proportion of phosphorus to iron is practically constant, the average analysis being: Fe, 33.62 per cent.; P, 0.73; or a phosphorus content of about 2.15 per cent. per unit of iron.

This proportion is so constant that the blast-furnace men rarely determine phosphorus in the smelting charges. They know that in a charge containing 30 per cent. iron there is approximately 2 per cent. of phosphorus per unit of iron, and that the pig iron will run about 1.8 per cent. phosphorus. Notwithstanding this constancy in the ore, the presence of silicon in the pig, varying from 0.3 to 0.8 per cent., causes variation in the percentage of phosphorus in the basic bessemer slags. These slags will usually average as follows: P₂O₅, 16.10; CaO, 47.05; MgO, 3.75; FeO, 11.35; MnO, 6.46; Al₂O₃, 7.60; SiO₂, 7. These slags are sold to manufacturers of fertilizers at a profit of about \$5 per metric ton, corresponding to

about 33c. per ton of ore smelted. As the cost of a ton of ore is in some cases in the neighborhood of this amount, it will be seen that the sale of the slags nearly pays for the mining of the ore in the most favorable instances.

OPEN-CUT AND HILLSIDE EXPLOITATION

The ferruginous veins are worked either by open cut, by galleries in the hillside, or by shafts. According to the French mining law of 1810, all the metallic mines, including coal, belong to the State, and concessions are granted by the government after the demandor has proved the existence of the mine, his financial capabilities, and also when the government engineers are satisfied the enterprise can be profitable. The owner of the ground above the mine has no right of preference on the mine except that where the iron ore can be worked by open cut it belongs to the owner of the ground down to the depth where the work is no longer on a paying basis. Below this point the mine is the property of the State and can be granted to another man than the owner

nel is to be extended to a total length of 10 km. It has advanced at the rate of 1 km. per year and at a cost of 350 fr. per m. The cost of haulage is 2 centimes per ton per kilometer.

Secondary galleries, shown as *R* in the accompanying sketch, are driven from the main haulage gallery. These secondary galleries are from 2 to 3 m. wide. At intervals of from 8 to 15 m. large galleries *I'* are mined with a width of 3 to 7 m. The angle between galleries *V* and *R* is determined by the inclination of the seam and the direction of the cleavage. The pillars thus formed are 5 to 8 m. wide and from 50 to 100 m. long, according to the conditions obtaining at the particular mine. They are mined in coming back toward the gallery *R*, the farthest pillars being cut down first. The rooms *C*, which are formed, are soon filled up by the caving of the roof, the rule being that every room is protected on two sides by ore *in situ*. As long as the gallery *R* is used for haulage, protective pillars *P* are maintained and are broken down later.

The size of the face of the pillars is

HAND DRILLING IN THE MOUTIERS MINE, BRIEY DISTRICT

ELECTRIC DRILLING AT THE MOUTIERS MINE

of the ground. Similar arrangements exist in the laws of Germany and Luxemburg, so that, in practice, the quarries of Lorraine iron ore are not deeper than to 17 m. Quarry properties are extensively worked in Luxemburg, and in France, near Longwy.

The hillside mines are numerous in Luxemburg, also in France, in the valleys of Alzette, Orne, and Moselle, and in the Orne valley in Germany. Some of the mines are worked from very long main galleries, such as that of the mine d'Hayange at Kuntange, which is 2 km. long and has a cross-section 3 m. high by 2.5 m. wide, that of the Société Stumm Frères from Entrange to Rochnovillers is 5.5 km. long, and that of the Société Roechling & Cie., from Beuvrange to Angevillers is 5.5 km. long with a section 2.5 m. high by 3.0 m. wide. In the latter electrically driven rope haulage is used. The Roechling tun-

nel is determined by the solidity of the roof, and also by the greater efficiency of the workmen on large faces. It was found that the greatest efficiency was obtained with a width of 8 to 10 m., but the character of the roof does not always allow even a width of 6 m. In some mines, such as that of Val-de-Fer, in the Bassin de Nancy, and that of Mont St. Martin, in the Bassin de Longwy, where regular and almost horizontal seams are met with, electric ore cutters and electric drills are used. The cutters are of the Morgan-Gardner type fitted with chains. The power required is from 20 to 40 h.p., according to the hardness of the ore and the speed. In a 2-m. seam they gave a monthly output of 6000 tons per machine at a lower cost than by hand. Several seams in a mine are worked at the same time and in some cases hand picking of the ore is necessary. Electric locomotives

and electric pumps are used in many mines and the galleries are usually lighted by electricity. The miners, however, have individual acetylene lamps. Ventilation is effected without fans by shafts connecting the different levels.

SHAFT MINES

The deep mines are located in the Bassin de Briey and furnish the excellent iron ore of that district. The advantages of this ore may be summarized as follows: (1) The ore is hard and compact and may be delivered to the blast furnace in lumps. (2) The percentage in phosphorus is always the same and is the very proportion convenient for producing basic bessemer pig iron, allowing the production of that quality without any analysis or mixture with other ores. (3) It gives valuable phosphorus slags as a by-product of the basic bessemer process. (4) Its richness

permits a smelting charge carrying 33 to 35 per cent. iron, instead of 28 to 30 per cent., as with other Lorraine ores, and a coke consumption 12 per cent. lower than the usual quantity. The corresponding economy is about 5.50 fr. per ton of ore, or 15 fr. per ton of pig iron for works situated close to the ore and buying its coke at 27 fr. per ton.

For a plant situated near the coal deposits in the North and buying the ore, the economy is 0.5 fr. per ton of ore. The ore of Briey is sold at a premium of 3 fr. over the other iron ores of the region. Its qualities, increased by its calcareous character, give it a wide market not only in France, but also in Belgium, Luxemburg and in Germany as far north as Westphalia. Some of the German steel producers are interested in these mines and special railway tariffs were introduced in Germany for the importation of the Briey ores.

The output in 1900 was over 3,000,000

pit dry while sinking a "deep-well pump" is installed. It consists of a number of pumps placed at different levels, the power being applied by a vertical rod as in Cornish pumps. Each pump feeds the pump placed above it. The first one is fed by a centrifugal sinking pump suspended in the pit and driven by a 3-phase motor. As the work advances the shaft is lined either with bricks or often with cast-iron panels, behind which a layer of cement is deposited to fill the space between it and the ground.

As soon as the ferruginous seams are reached the permanent pumps are installed. As the life of the mine depends upon the reliability of these pumps, only first-class machinery is installed. They are steam-driven and usually have a capacity of about 10 cu.m. per min. However, a plant of 28-cu.m. capacity per minute has been installed in one mine at a cost of \$200,000. The working cost is low, being 3 to 4 centimes (0.6 to 0.8c.) per cu.m.

ore cars having a capacity of about 2 metric tons of ore; the daily output is usually about 2000 tons in 20 hours. The method of working the seams is the same as in the case of hillside mines.

The sinking of the two shafts to 200 m. and their complete equipment with the necessary machines, buildings, workmen's houses, general expenses, etc., cost as a rule about \$1,000,000. To prevent damage to the buildings on the surface, large pillars are left in the mine to avoid as far as possible the effects of the caving in of the roof. The installation of hydraulic filling plants has been carefully considered by the mine owners and the problem has been solved at the Auboué mine by using granulated shgs and a marl- ish limestone which can be got cheaply in the country. The cost amounts to 10c. per ton of ore.

At some of the mines large electric power plants have been installed for supplying power to the various parts of the

UNDERGROUND ELECTRIC HAULAGE IN THE BRIEY DISTRICT

UNDERGROUND LAVATORY AT THE MOUTIERS IRON MINE

metric tons with only four mines (Jouff, Homécourt, Auboué, Moutiers) in operation. At present 10 mines are at work and others are preparing for production. There will soon be 19 mines at work in this district which will make a large increase in the output. All these mines belong to iron and steel producers and, up to 1909, 43 mines have been granted to 32 companies. Through the courtesy of Georges Rolland, president of the Acieries de Longwy, the accompanying table is given, presenting some particulars about these deep mines at the end of 1908. The concessions granted by the government have an average area of 900 hectares (about 2223 acres). They are usually worked by means of one shaft for hoisting and one for the proper ventilation of the mine. As usual in France these shafts are circular with a diameter of 5m. generally.

HANDLING THE WATER

As explained above, the main difficulty that was met with in sinking the shafts was the presence of water. To keep the

when pumping against a head of 100 meters.

As the quantity of water to be pumped out may double in the wet season, a second pump of same capacity but of cheaper type is always installed. It is usually a multi-stage centrifugal pump, electrically driven. In addition the set of sinking pumps is kept for use in case of breakage of one of the other pumps.

The shaft used for ventilation is not sunk until the first one is completely fitted up with all the pumping machinery. A drill hole is then made in the center of the proposed shaft and a gallery is driven to connect the main shaft with the bottom of the bore hole. Thus all the water that is met with in sinking the second shaft goes down through the bore hole and gallery to the bottom of the main shaft whence it is pumped out by the existing machinery.

MINE EQUIPMENT AND COSTS

The main shaft is equipped with the best machinery, the cages contain two

property. As all the mine owners are iron smelters most of the power plants are driven from power obtained by gas engines utilizing the gas from the blast furnaces, with an economy of 50 per cent. over steam power. There were in 1906, 5500 workmen employed in the mines. The laborers are paid 3 fr. and the best miners 10 to 12 fr. The average is 5 fr. The efficiency of a miner is calculated to be about 1000 tons of ore per year. All the mines are connected with the lines of the Eastern Railway Company by private tracks, the longest of which does not exceed 3 kilometers.

In the accompanying table are some details of the cost of one metric ton of iron ore delivered in a car on the nearest lines of the Eastern Railway Company under various conditions in France, according to Mr. Bailly.

Other mines 180 m. deep with an annual output of 550,000 tons from a 3-m. calcareous seam, and pumping 12 cm. m. per min., get a cost of 60c. per ton, of which 15c. is due to pumping by steam. It is estimated that at 200 m. with an annual output of 600,000 tons and pumping of 10 cm. m. per min., the cost will be as follows: Mining, transport and maintenance,

PLAN OF THE GALLERIES

nance, 35c.; general expenses, 3; pumping (steam), 14; depreciation on plant in 20 years, 13; total, 65 cents.

In France the iron and steel works, treating the ore of this district in 1907, embraced 21 reduction plants belonging to 19 companies. Ten of these companies produce only pig iron. The number of blast furnaces was 76, of which 68 were running, producing 2,500,000 metric tons of pig iron. The steel works comprised 30 Thomas converters, 8 open hearth furnaces, 31 steam hammers and 43 rolling mills, giving an output of 1,212,500 tons of steel, or 51 per cent of the French steel production.

Figures collected for THE MINERAL INDUSTRY show that the output of carborundum in the United States in 1908 was 4,907,170 lb., valued at \$294,430. In 1907 the production was 7,532,670 lb., valued at \$451,960.

The Chinese government proposes to develop the oilfields of Shensi. Foreign capital is not wanted. If Chinese capital is not to be had, the government will undertake the work.

The Broken Hill Proprietary Company

The report of this New South Wales company for the half-year ended Nov. 30, 1908, and the chairman's address to the shareholders discuss the labor troubles that occurred at the commencement of the year and which led to a stoppage of operations. At the close of 1906, owing to the high price then ruling for lead, the directors granted a general advance of wages, averaging about 12½ per cent. The agreement made with the men was for two years and was to expire Dec. 31, 1908. During 1908 prices fell, and the directors decided that a return to the old scale of wages paid in 1906 was necessary, in order to make the company's business remunerative.

The Mineowner's Union was not unanimous about reducing the scale of wages and the other Broken Hill companies, with the exception of Block 10 Company, agreed to continue the advance given under the previous two years' agreement. The Proprietary Company and the Block 10 Company made, however, an offer to the men to pay on the previous basis with a sliding scale based on the price of lead, which offer was declined by the miners. The dispute was then taken to the Arbitration Court, after an offer had been made by the directors to abide by the award of that Court and had been refused by the miners' union. The Arbitration Court decided in favor of the higher wages as paid by the other mining companies. Against this decision the directors have appealed to the High Court, being advised by their counsel that the judge had gone beyond his jurisdiction in his award. The decision of the High Court is being awaited. The scale of wages acceptable to the union depends on an assumed "living wage." On this point the chairman makes the following remarks. "The term 'living wage,' as referred to by Mr. Justice Higgins, is no doubt a most pleasant sounding term in theory, but in practice it is quite impracticable. The factor that guides in this matter must be what can the worker give in labor for the value he receives, and if the industry cannot pay the rate fixed by the worker, then the industry must be discontinued and the worker be without employment. No legislation or arbitration court can artificially set aside for any length of time the natural law governing such matters, and all attempts in this direction must ultimately end in failure and disaster; as what is the value of an award on paper with no employment?"

Before the Arbitration Court sat, an undertaking was given by the miners' union to accept the award of the court, but the company merely undertook to resume operations, in accordance with the courts' award, as far as regards the pro-

duction of zinc concentrates and so far as regards the smelting and treatment of lead concentrates purchased from other companies. These latter contracts will expire with the present year, except one which expires in March next year. The company would not assure the court that it would resume full operations as before. The life of the mine as an ore-producing concern is estimated at five years, and only 2½ years at the present rate of extraction. A continuation of operations on a reduced scale appears, however, to have been promised, and on this understanding the court considered the case; and its main object being to decide what was a proper wage for human labor under the conditions prevailing and not to dictate to the company what work should be carried on. The award of the court, as stated above, was not accepted by the company, on the plea that the judge had exceeded his powers and an appeal to the High Court was lodged.

With regard to the operations of the company the first unit of the smelter plant at Port Pirie was completed during the half-year and an addition of nine furnaces decided on. The smelters put through an increased quantity of material, treating 132,979 tons as against 115,266 tons for the preceding half-year. The refinery turned out from the bullion treated 47,833 tons of soft lead, 2,589,416 oz. fine silver and 1054 oz. gold. The disposal of the lead for the six months ending Nov. 30, 1908, has been as follows: To Europe, 38,852 tons; to India China and Japan, 7508; to Australia and New Zealand, 3750; total, 50,110 tons. Trade with the Far East has been well maintained.

In the mine development work in the lower levels has not proved as satisfactory as was anticipated, but at the 900-ft. level good ore, though of no great extent, is being found.

The average prices received during the six months were for lead £13 4s. 7d. per ton; for silver (standard) £3.93d. The gross profit amounted to £34,430, and the net profit to £25,701. The fire in Block 11 is not giving any anxiety and is not likely to do so in the future. The ore reserves, which on May 31, 1908, were shown as 3,000,000 tons have been reduced to 2,735,153 tons by the mining during the six months of 264,847 tons. During the half year no considerable new ore-bodies have been found. The average cost of mining, inclusive of development work, etc., has been 15s. per ton or about 1s. 8d. per ton less than in the preceding half-year.

According to *The Iron Age*, May 6, 1909, the largest ore freighter, the "Shenango," was launched at Detroit, Mich., May 1. The boat is 607 ft. long, 58-ft. beam and 32 ft. deep. Capacity, 13,000 tons of ore or coal, or 488,000 bushels of wheat.

The Zacatecas District and Its Relation to Guanajuato and Other Camps

By C. W. Botsford*

This is not an article on the Zacatecas district in its entirety, but merely some notes on the geology near the city of Zacatecas, and its relation to that of Guanajuato and other parts of Mexico. The similarity between many of these districts in Central Mexico is very pronounced especially in the succession of the formations and the faulting and vein-systems.

Topographically, the Zacatecas area is situated in a rather low range of mountains that rise about 1000 ft. above the central plateau of Mexico. These are well rounded and smoothed by the action of the elements and fade gradually away into the smooth low foothills, and these gradually into the surrounding plains. Extensive faulting has occurred here, but it is not perceptible in the present topography.

SUCCESION OF FORMATIONS

Cretaceous shales have been exposed by erosion both to the east and west of the city. This is the oldest formation exposed in the district. They are the same black, calcareous, thinly-bedded shales that are found to such extent at Guanajuato. They have been much folded and bent, and sericitization and silicification has been extensive in some parts of the district. These shales underlie the whole country but have only been exposed near the borders of the mineralized area. They were followed by much erosion before the volcanic activity began.

The first volcanic activity produced great quantities of andesitic breccias. These consolidated breccias are precisely similar in appearance and composition to the rock at Guanajuato, called the Guanajuato conglomerate. At Zacatecas, these breccias are on the average a little finer and contain greater percentages of ash and tuff than the average agglomerate at Guanajuato. There is also, I think, more perfect evidence of water action.

At Zacatecas, the series of rhyolitic and andesitic breccias present at Guanajuato do not occur. These formations, I think, are always local and are the indications of an intermediate and comparatively quiescent stage when only a few local volcanic districts were in eruption.

The diorite intrusion followed the andesitic breccias probably at a lapse of considerable time. Near the city, this intrusion seems to have forced its way in between the shales and the conglomerate and to have penetrated irregularly upward. There has been much contact

metamorphism, producing many varieties of changes from the red agglomerates into greenish, indurated rocks similar to the La Luz schists of Guanajuato. This change is well exposed in the streets at the eastern end of the city and along the road to Guadalupe.

Following the diorite intrusion came the folding, followed by extensive erosion. At this time Zacatecas probably assumed approximately its present topography.

The later rhyolites mark the resumption of volcanic activity. They are a very extensive series of rhyolitic breccias and tuffs, the latter called *cantera* in many parts of Mexico. This formation from Zacatecas to the north has only been left by the erosion on the top of the Bufo. South of the town the whole country is still capped by this material. This formation was also present at Guanajuato but has been largely removed by erosion except in a few areas on the tops of the mountains.

In tabular form the succession of for-

of Central Mexico from the State of Jalisco northward to Durango.

Following these came a comparatively quiet period when the volcanic activity only occurred in local districts. This was the time of the series of eruptions at Guanajuato, the Pinguico rhyolites and andesites, which are missing at Zacatecas. The last effort of this first stage of vulcanism was, I think, the intrusion of the granites and diorites. These have evidently been the cause of many of the ore deposits.

After this final effort of the intrusions, the country seems to have had a long rest from volcanic disturbances. Then came the principal faulting caused by the settlement and adjustment of the strains resulting from the long period of vulcanism. During this long rest extensive erosion took place.

The second period of vulcanism gave the later rhyolites. Their extent was enormous, nearly the whole of the western part of Mexico having been covered by these eruptives. From Guerrero on the

CANTERA VEIN AND SURROUNDING FORMATIONS

mations at both Zacatecas and Guanajuato, from the youngest down, are as shown in the accompanying table.

SUCCESION OF FORMATIONS AT ZACATECAS AND GUANAJUATO.

Cretaceous shales	Cretaceous shales	Cretaceous

TWO STAGES OF VULCANISM

There seems to have been two well defined stages of volcanic activity in Central Mexico, each of which is traceable over extensive areas. The older was the long series of andesitic eruptions which have resulted in the Guanajuato agglomerate and similar formations in various parts of Mexico. These rocks are widespread and persistent in large areas

south, far into Chihuahua on the north, and from the eastern parts of the States of San Luis Potosi and Guanajuato to the Pacific Slope on the west, the whole country has been generally covered.

The principal development of these rhyolites was along the western axis of the Sierra Madre. Known thicknesses of 5000 ft. are common for this formation. Very recent basaltic flows have followed these rhyolites but are of only local interest.

FAULTING AND VEIN-FORMATION

The principal faults of both Zacatecas and Guanajuato are those striking northwest-southeast, and dipping westwardly. These are always normal faults. This system of faults is persistent and extensive through all the central portion of Mexico. At Zacatecas this system is illustrated by the Cantera and Veta Grande veins. The Mala Noche vein dips in the opposite direction, and is more in the nature of a cross-vein and was probably caused by relieving a twisted strain. As at Guanajuato, the ore deposits are replacements along these fault planes. At Zacatecas, unlike Guanajuato, the ores

*Mining engineer, Springville, N. Y.

tend to run into base-metals. The Veta Grande and the west end of the Cantera vein carry only silver and a small content of gold. The Magistral and Mala Noche veins run into copper and iron bases; at

INDUSTRY show that the production of coal in the United States during 1908 amounted to 414,454,064 short tons (\$541,602,127), as compared with 480,033,045 short tons (\$640,803,723) in 1907. Of the

in 1907 was \$1.99, and of the bituminous coal \$1.19 per short ton, the production being 80,341,832 short tons of the former variety and 393,692,113 short tons of the latter.

Goldfield and the Goldfield District of Nevada

Since Discovery of Goldfield Approximately 50 Per Cent. of the State's Output of Gold Has Come from This Camp; Dividends Paid, \$12,000,000

BY JOHN TYSSOWSKI

During recent years mining developments in Nevada have attracted widespread attention. The State has once more been through a boom and this time has weathered the storm. In the late spring of 1903 Goldfield was discovered, and by the end of that year had already begun to produce precious metals. Since 1904 this one camp has far outdistanced all the remainder of the State as a producer of gold.

The accompanying tables show, for the years 1902-1908, inclusive, the commercial value of the gold, silver, and total gold-silver production of Nevada, and of Goldfield alone; also the percentage that Goldfield has contributed to the total output of the State. It may be noted that Goldfield has produced \$27,000,000 in the last five years (1904-1908), or 48 per cent. of Nevada's total gold yield for that period. As

tain order. The dispute was at last satisfactorily arranged for both sides.

Visitors to southern Nevada formerly came away with the impression that Goldfield was merely a temporary camp. Comparison was often made with Tonopah, bringing out the permanent and solid appearance of the older camps as compared with the makeshift conditions found in Goldfield. This was true at first, when most of the properties were being worked on leases, but it does not apply at present.

The present population of Goldfield is estimated at 6000 and is of a much more permanent character than it was during the rush days when it was supposed to amount to about 10,000. The completion of the proposed railroad to connect Goldfield with Ely, will, no doubt, add materially to Goldfield's prosperity.

the only satisfactory one, of a mining camp's permanency, is its record as a dividend payer. Already this year one company, the Goldfield Consolidated, has paid a dividend of \$1,063,803.90, and has declared another of equal amount (3 per cent.), payable July 31. The dividends paid by Goldfield companies in 1908, a year in which many companies all over the world discontinued dividends, totaled \$1,578,500, made up as follows: Florence Goldfield, \$420,000; Engineer's Lease, \$570,000; Rogers' Syndicate, \$300,000; Mohawk Jumbo, \$78,000; Frances Mohawk, \$45,500; Florence Annex, \$50,000; Red Top Consolidated, \$20,000; Little Florence, \$30,000; Mohawk Combination, \$65,000. Other dividends, of which I have no record, may have been paid. This is a splendid record when it is considered that the two largest properties in the

Totals(c)...	\$51,712,017	\$27,117,480	(b)48	\$20,849,417	\$116,375	(b)0.52	\$72,561,434	\$27,233,855	(b)39

(a) Figures used represent mine reports as agreed upon by Director of the Mint and the U. S. Geological Survey. (b) Average percentage for last five years. (c) Only years 1904-1908 inclusive are included in totals.

a producer of silver, it is seen that Goldfield is inconsequential, contributing only 0.52 per cent. of the total output of the State.

The growth of the mines of Goldfield has been vigorous and constant. Only in 1905 and again in 1908 did the production fail to increase over that of former years. However, the cause for this is plainly apparent. In 1905, the year after the first wild rush into the district, people began to put in permanent equipment and to develop their properties; leasing was also less active, and companies began to store low-grade ore to await completion of reduction works on the ground. In 1908 the setback was due to the financial depression. At the same time when we consider that the year's production from Goldfield represented only nine months' work, it is evident that even in hard times the camp continued to grow. During the first three months of 1903, Goldfield suffered from a bitter labor controversy, and it was at this time that General Funston took the regulars into Goldfield in order to main-

tain order. The Goldfield mills, when those under construction are completed, will be capable of treating 1000 tons of ore per day. The Nevada Reduction has a capacity of 100 tons; the Combination, 80 tons; the new Goldfield Consolidated, 500 tons; and the Florence, 200 tons. The new Goldfield Consolidated and Florence mills are of the latest type; they have been described in the JOURNAL.¹ The accompanying map and index sheet show the location of the greater part of the mining claims in the Goldfield district. The area included in the map is about $10\frac{1}{2} \times 7\frac{1}{4}$ miles, and 437 claims are shown. On the index sheet several of the companies have no number in the column designating the claims on the map. This is accounted for by the fact that the claims are not located within the area shown by the map, or else the company has been merged into some other one, under the name of which it is to be found.

The best indication, and to the public

¹Sept. 5, 1908.

camp, the Goldfield Consolidated and the Florence companies, were building new mills and did not pay dividends.

The dividends declared in 1907 amounted to nearly \$1,500,000. Previous to 1908 almost \$8,000,000 had been paid to the investing public by Goldfield companies. Thus, to date the mines have paid dividends, amounting to approximately \$12,000,000.

It is early to form an idea of what the 1909 production of Goldfield will be; judging from the returns to date, however, this year will be a record breaker. The output for four weeks selected at random is as follows: Week ending March 13, \$220,000; March 20, \$332,000; April 13, \$507,850; April 27, \$600,650. These figures, which are possibly a little high, show a steadily increasing output; even taking \$300,000 as an average week's production, the year's total will amount to \$15,600,000, or over 200 per cent. of the total for 1908. At present the Goldfield Consolidated and Florence are the largest producers in the camp.

A Matte-Separating Forehearth

By E. JACOBS*

The settler in use at the Tye Copper Company's smelting works at Ladysmith, Vancouver Island, B. C., is so constructed as to provide for a continuous flow of matte as well as slag; consequently the removal of the matte by tapping at intervals is obviated. This provision is simply an adaptation of the old Orford style of separator to a water-jacketed receiver, the receiver being of a much larger size than those formerly used. It is, further, an improvement on the Orford

the bottom, this space is filled in with chrome brick.

The level of the matte is controlled by regulating the height of the slag outlet. For instance, if it be desired to increase the flow of matte, a ball of clay is pressed into the slag spout; or to reduce it, this outlet is opened up. As nearly as practicable a depth of 10 in. of matte is maintained in the settler.

The size of settler ordinarily used at the Tye company's works is 4 ft. wide by 12 ft. long, but the construction of a much larger one is contemplated. This matte-separating arrangement has been in use here for three years, and so far as known to the manager of the smelter, W.

as in the ordinary tapping operation) and in the saving of tapping clay.

Platinum in Borax

J. G. Rose (*Chem. News*, Aug. 1908) in assaying various samples found traces of platinum, where such results were rather unexpected and he then proceeded to investigate the reagents used in the assays. The sodium bicarbonate having previously been examined for platinum, the borax and litharge were tested. The litharge was soon proved to be platinum free but not so with the borax. Further

DETAILS OF MATTE SEPARATING FOREHEARTH IN USE AT SMELTERY OF TYE COPPER COMPANY, VANCOUVER ISLAND, B. C.

separator in that the matte compartment is placed outside the main receiver, so that in case of accident it is practicable to remove this part without interfering with the working of the furnace, since the receiver is also fitted with the ordinary tapping jackets, one on each side, for use in such an emergency until the necessary repairs shall have been made to the matte-separator compartment mentioned.

The matte compartment, the position of which is shown in an accompanying illustration, is 24 in. square and is lined with 8 in. of brick. The opening between the settler and this outside compartment is 24x22 in., but with the exception of a connecting channel 6 in. square, at

J. Watson, he was the first to use it in this way. It has been found to work very satisfactorily, so much so that during the three years the matte compartment has been frozen up only two or three times, and then because of the high zinc content of the matte, which sometimes was as much as 23 per cent. ZnS.

Among the advantages afforded by the use of this matte separator are the elimination of danger of men being burned when tapping, the much cleaner slag made (this causing a saving which in one month more than pays for the cost of installation), the economy effected in the services of a taper being dispensed with in all of the three shifts, the reduction in the wear and tear of matte pots (the stream of matte not striking the side of the pot

tests showed the borax to contain 0.00013 per cent. platinum. Tests were then made to ascertain if this amount of platinum could be introduced into the borax through the fusing of the same in platinum vessels. These tests conclusively proved that fused borax has a very distinct action on platinum ware and platinum determinations made with borax prepared in platinum vessels should be viewed with suspicion.

Statistics compiled for THE MINERAL INDUSTRY show that there was an increase in the output of coppers in the United States during 1908 over that of 1907, amounting to \$503 short tons, worth \$94,103. The total 1908 production was 35,334 short tons, valued at \$388,674.

*Victoria, B. C.

California Oil and Asphalt Lands

SPECIAL CORRESPONDENCE

In the House of Representatives at Washington, Mr. Smith, of California, has introduced a bill (H. R. 9904) to provide for the disposal of lands chiefly valuable for oil and asphaltum. This has been referred to the Committee on Public Lands, and it is understood will be pushed next winter.

The bill provides that the public lands of the United States in the State of California chiefly valuable for mineral oil or asphaltum may be acquired under the provisions of the proposed act and may not henceforward be located as placer-mining claims. The bill then goes on to specify that any citizen, actual or intending, of the United States may file a declaration with the register and receiver of the land district, wherein is situated the land that he

phalum in commercial quantities, etc.; but it is further provided, "that if there are any veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits known to exist at date of filing such application for patent, title thereto shall not pass under any application, entry, or patent under the provisions of this act, but are hereby expressly declared to be reserved therefrom, and such known veins or lodes shall be subject to location and entry by any qualified person or persons under the provisions of the existing United States mining laws applicable thereto; provided, however, that any declarant who discovers any vein or lode bearing asphaltum, gilsonite, elaterite, or other like substances within the limits of the land included in his declaration or entry under this act shall have the preferential right for a period of 90 days after discovery of such vein or lode within which to locate the same under the provisions

the public interest." In replying to the resolution, Secretary Ballinger, however, finds that it is incompatible with the public interest to make known the whole report, and he therefore, transmits, as noted, merely the conclusions. The reasons which have led him to hold back the bulk of the report are that the investigation was undertaken largely with a view to the better planning of the work of the Geological Survey in this country. With this in mind it was intended that the data should be held confidential, and assurances to that effect were given to the owners of the Mexican oil wells. Mr. Ballinger points out that at present mines and other natural resources in private ownership are open to inspection by Government agents, and that it is extremely desirable they should continue to be so. This, however, cannot be the case unless the good will and confidence of the miners in the intentions of the Government are maintained, barring, of course, the possibility of legislation compulsorily opening the mines to government examination.

In presenting the conclusions arrived at by Mr. Hayes, Mr. Ballinger says that while the Mexican fields promise to yield a large quantity of crude oil, its quality is such that it cannot compete under present conditions in the markets of the United States or Europe with the higher-grade petroleum of the Appalachian, Illinois, or Mid-Continent fields. Further, the conditions are such that the demand for fuel oil and refined products in Mexico exceeds the supply available at present, or in sight. There is little coal in Mexico, and the railroads, now dependent chiefly on Texas, Oklahoma and English coal, could consume several times the present production of oil if it were generally adopted as fuel. The increased production in the Mexican fields, therefore, will affect the United States by reducing the demand for coal, by reducing the demand for high-grade crude oil in refining to supply the local market, and to some extent by competing in the European market with American refined products. Finally, the conditions in the Mexican fields are found to be unfavorable to the small operator, and it is regarded as highly probable that production as well as refining will remain in the hands of a few strong companies. The geological conditions under which the oil occurs are such as to increase the hazards and uncertainties encountered in the development of an oilfield, and it is probable that both the difficulty of securing a steady supply of oil and the average cost of production will be correspondingly increased.

In 1908 the production of chrome ore in the United States, as shown by figures collected for THE MINERAL INDUSTRY, was 280 long tons valued at \$5600. This was a decrease from the 1907 production of 335 long tons valued at \$5620.

MATTE-SEPARATING FOREHEARTH IN USE AT TYEE COPPER COMPANY'S SMELTER AT LADYSMITH, VANCOUVER ISLAND, B. C.

intends to claim, that he intends to improve the land for oil or asphaltum, describing the land in a tract not exceeding 160 acres. In no case shall a claim be more than one mile in length. Upon filing the declaration the declarant shall pay the receiver a fee equal to 25c. per acre. Nothing, however, is to abridge the right to enter the lands subsequently for the purpose of discovery and development of metalliferous minerals, or the assertion of a mineral claim thereto. Neither shall the proceedings give to the claimant before patent the right to the surface of the land for agricultural, grazing, or any other purpose, nor the right to take wood from the surface of the land. At any time within three years the claimant may make application for patent and the application shall show that drillings have been made to produce oil or as-

phalum in commercial quantities, etc.; but it is further provided, "that if there are any veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits known to exist at date of filing such application for patent, title thereto shall not pass under any application, entry, or patent under the provisions of this act, but are hereby expressly declared to be reserved therefrom, and such known veins or lodes shall be subject to location and entry by any qualified person or persons under the provisions of the existing United States mining laws applicable thereto; provided, however, that any declarant who discovers any vein or lode bearing asphaltum, gilsonite, elaterite, or other like substances within the limits of the land included in his declaration or entry under this act shall have the preferential right for a period of 90 days after discovery of such vein or lode within which to locate the same under the provisions

Mexican Oilfields

SPECIAL CORRESPONDENCE

In response to a resolution offered some days ago by Senator Cummins, of Iowa, and subsequently passed by the Senate, the Geological Survey has sent to the Senate through the Secretary of the Interior a digest of the conclusions arrived at by C. W. Hayes, chief geologist, in a tour of the Mexican oilfields. The Cummins resolution made request for the full report of Mr. Hayes with, however, the usual proviso, "if not incompatible with

Mining for Gems in Brazil

By A. S. ATKINSON*

In the past few years several American companies have been organized for mining operations in Brazil with the chief object in view of working some of the old abandoned mines and opening up new ones that yield gems suitable for the jewelry trade. These gems are profitable for that large trade in cheap jewelry which has steadily expanded in recent years in this country, and Brazil offers a fertile field for obtaining the raw material. The trade is naturally influenced materially by the caprices of fashion, but generally speaking the demand is fairly constant for tourmaline, garnets, agates, rock crystal, amethysts and topazes.

The superficial deposits of most of these gems have been exhausted in this country, and the difficulty of mining for them at greater depths has increased their value. In most of the mining regions of Brazil the stones are still near the surface, and in many parts they can be extracted without great work or difficulty. Another difficulty in mining for American gems of this nature is that most of the perfect stones have been mined, and those remaining are for the most part either small or marked with some flaws; also the perfectly colored stones are getting rarer every day, even those most suitable for the ordinary jewelry trade.

These conditions of the market supply determined the American companies to turn their attention to Brazil as a wide field offering profitable returns. The results of this investment have not been without good returns and some excellent experience which may lead to more important developments in the future. Mining in Brazil by the natives is still in a primitive condition, and it is only outside capital and brains that develop the mines to any important extent. Brazil has for years been exporting these gems, but they were obtained chiefly through desultory work in picking them up from the surface. Yet in the mining regions good stones can be found a short distance below the surface by expert miners.

TOURMALINE MINING

Mining for tourmaline is one of the most important industries of Brazil. In reality, however, the deposits have only been superficially worked. The tourmaline zone is quite extensive, extending from Itamarandiba and running northeast as far as the Piahy river, a branch of the Arassuahy, and thence west and northwest as far as Boqueirão, and San Antonio das Salinas. In the municipal districts of the Theophilo Ottoni and Aras-

suahy there are about 800 persons engaged in mining for tourmaline alone. The stones are found throughout the lower basin of the Arassuahy and in the valley of Rio Doce, also along the rivers Itambacury, Urubú, Setúhal and Caihao. The gems are found in the veins of granite, quartz, pegmatite and gneiss along the river banks and are washed out and picked up by the miners in considerable quantities.

At Theophilo Ottoni an active mine is in operation, and systematic work is done to extract the gems. The deposits occur in a forest under a layer of earth several feet deep. The layer of earth is removed, and the stones are then found in a bed of gravel. The stones found here are of an ordinary bottle green, and hence are not very valuable, but the quantities in which they are found makes the work profitable.

Much better tourmalines are extracted from the big mine of Larangeiras at Arassuahy in the district of Itinga. This mine has been successfully operated for about nine years, and the supply of stones continues good. Perfectly transparent green tourmalines are found here, and they command good prices. At San Miguel not far from this mine the blue and red varieties of tourmaline have more recently been unearthed. Unfortunately few of these are found to be perfect. The red ones invariably show flaws and the blue ones are not transparent. Most of these stones are traversed by cracks which practically spoil them for the best jewelry purposes. Some of these stones are of unusual size, and in spite of the flaws they can be cut advantageously into a number of smaller ones.

Good red tourmalines are in fair demand in this country at prices which make their mining profitable. A mining company composed of natives and Americans has been in operation on the Piahy river for the past two years, and some very fair specimens of red tourmalines have been received from them. The coloring of a tourmaline determines its price, as much as its flawlessness. Clear rich transparency and beautiful coloring makes a small-sized tourmaline more valuable than one twice the size but lacking in color and transparency.

AQUAMARINES

Some fine aquamarines have been mined in various parts of Brazil, and one a few years ago was taken from a mine near Arassuahy that weighed nearly six pounds. The record, however, was one that weighed 15 pounds. It was of the green variety and was mined as far back as 1814. This stone was eventually cut up and dispersed. We have the authority of Eschwege that it weighed 15 pounds, but that is all. If the stone was of such a size and correspondingly perfect and well colored it is a pity that it was not preserved intact. Some very large

and handsome aquamarines are obtained today from the Brazilian mines, and one American company has exhibited several specimens of remarkable coloring ranging from half a pound to several times this weight. The best aquamarines, however, come from the island of Alegre. Beautifully colored aquamarines are found there in crystals of great lustre. These are exhibited at the different ports of Brazil to visitors to show them the richness of the gem deposits of the country. Frequently prospectors are deceived as to their origin, and they are induced to make extensive searches for similar stones in the tourmaline districts.

Many American prospectors are today going into Brazil with the idea of locating gem mines, and the need of accurate information is essential. Like all other mining countries, wonderful stories may be heard about picking up priceless Brazilian diamonds, topazes, and amethysts. But like all such stories they generally simmer down to only a very small grain of truth. On the other hand the government of Brazil has so little accurate knowledge of its own mining resources that the prospector must often follow ordinary rumors to get anywhere.

As fashion dictates the value of stones to a large extent, the miner for gems must consider the vagaries of a fickle market; but most of the stones of commerce sooner or later come into fashion again after having passed through a temporary eclipse. Amethysts have not been in as active demand as tourmalines and aquamarines for some time, but they are pretty sure to return to a fair state of popularity. The mining of amethysts has suffered a decline in Brazil as a result of this change in fashion, but good ones are always in demand. Similarly mining for topazes is conducted on a small scale in Brazil, but a revival of interest has been manifested in the mines in the last year.

TOPAZ MINES

The old mines of Boa Vista and Seramenlain in the basin of the Arassuahy river, have been reopened by a new company, and some beautiful topazes are being obtained. The old open-cut method of mining has been abandoned, and deep mining is carried on with success here and at Jose Correa and Caxambu. The gems are extracted from a gravel bed about 20 ft. deep. The topazes show a great variation in coloring and size. Some are small and full of flaws, and others changing from a pale yellow to a deep rose shade and so large and transparent that they are of the greatest value. There is exhibited at the national museum at Rio Janeiro a topaz mined at Ouro Preto in the basin of the Jequitinhonha river that weighs almost 2000 grams. But its size is not more significant than its beautiful color, perfect transparency, and absolutely flawless condition. It was

*P. O. Box 1180, New York City.

one of the handsomest gems ever mined in Brazil or any other country.

There is a yellow quartz which comes from the state of Goyaz which resembles the topaz and is largely exported to meet the demands of the cheap jewelry trade. Thousands of stones in use which pass as topazes are only yellow quartz. It is mined on a large scale in Brazil and has really hurt the topaz miners. There is another gem occasionally found in the topaz mines. It is a hydrous silicate of aluminum and glucinum, and known as euclase. This is of a pale blue or green color and of vitreous lustre. It is a stone of considerable rarity and value, and its presence is always welcomed by miners. There is a special demand for good specimens for museums, as well as for the better class jewelry trade. The best specimens of euclase have been mined at Boa Vista and Capao da Lana.

AGATES AND OTHER GEM MINERALS

Agates, garnets and rock crystal are obtained in considerable quantities from many parts of Brazil, but the size and quality of the gems are not always satisfactory. The garnets are obtained chiefly in the valley of Santa Maria, a branch of the Calhao river, and along the shores of the tributaries of the Urubú river. They are rather small and belong to the varieties known as pyrope and almandine. The stones are of a dark red, and if larger they would have more general demand.

The agates of Brazil run from chalcedony to onyx and are quite abundant in Rio Grande do Sul and several other districts of the country. In the neighborhood of Uruguayana there are some of the richest beds of agates in the world. The beds stretch over a large area and the supply of gem stones is abundant, but it is the coloring and size of the stones which make them so attractive. They come in wonderful carnelians of a deep red color, and some of them are of unusual size and flawless beauty. Large quantities of these agates are sent to Germany; thence they find their way into this country in jewelry.

The best rock crystal and quartz are found in the famous mountain Cristaes in the State of Goyaz. The rare specimens extracted and cut for the trade indicate the output of these mines. In spite of the fact that the mines have been worked for many decades, the output is large today and many deposits, not located or worked, still await the prospector.

The chrysolites in spite of their beautiful yellowish green color are not of much value as gems today but these minerals are found in the valley of the Gravata river in the most wonderful abundance. They are really decomposed chrysolite and called by the miners *cambalaxa*. The stones are found in gravel deposits along the river and were formed by the decomposition of the quartz veins that traverse the gneiss rocks. The stones are

beautiful and should be of use in certain branches of the jewelry trade.

GENERAL CONDITIONS

Unfortunately most of the gems found in Brazil are subject to an export tax which makes their marketing outside of the country less profitable. This tax varies with the stones, but it is not usually of a prohibitive nature. Very fine specimens could be shipped away with great profit, but the common stones would hardly pay. Gem mining has in the past decade become a profitable industry in many parts of the world, and the enormous demand by the cheaper jewelry trade for stones which can be utilized for ornament at no great expense has stimulated prospectors to study carefully profitable fields of exploitation of such stones as those mentioned.

part they are content to scratch the surface of the land or dig a few inches into the gravel beds for the stones and if not uncovered, they pass on to new regions.

Oxidizing Furnace for Pulverized Ores

L. S. Hughes, of Joplin, Mo., describes (British Pat. 16,521 of 1908) a furnace for oxidizing pulverized ores which are carried through the furnace chamber by an air blast and maintained at a comparatively low temperature preventing their fusion, or the decomposition of substances in the ore that would injuriously affect the product. The accompanying illustration shows a sectional elevation of

OXIDIZING FURNACE FOR PULVERIZED ORES

Diamonds, rubies and the more precious gems are not considered in this paper, for they are of comparatively rare occurrence, but tourmaline, aquamarines, topazes, amethysts, garnets, agates and rock crystal can be mined systematically in restricted areas at a good profit. They form the basis of the cheap jewelry trade and must continue to improve in value as new methods of using them are invented. Mines that will yield an abundance of such stones regularly cannot fail to prove profitable in the long run, much more so in many respects than a mine where only the more precious gems are occasionally found.

Brazil offers a field for gem mining that is only partly understood, and, one might say, only half explored. Within its great mountainous stretches of mining land there must be wrapped up treasures in the form of precious and semi-precious stones. The native population is slow to realize and slower to adopt modern methods of mining for these products. For the most

part they are content to scratch the surface of the land or dig a few inches into the gravel beds for the stones and if not uncovered, they pass on to new regions.

Around the lower part of the furnace chamber is a gas-burner ring provided with nozzles which are inclined upward so that the flame issuing from them will not impinge upon oppositely disposed tubes. The pulverized ore is fed into the hopper at the side and then passes into a chute with a trough-like end projecting nearly to the center of the furnace, so as to deliver the ore directly into the air jet. Below the hopper is a gate for regulating the feeding of the ore, and on the outside of the chute is a rapping or vibrating device for keeping the hopper and chute in a state of vibration.

A Novel Coal and Stone-Cutting Process

A System Based on the Use of Driven Cables Carrying Tempered Steel Cutting Points, Whereby a 50 Per Cent. Saving Is Possible

BY ALFRED GRADENWITZ *

The coal- and stone-cutting process here described, was invented by Messrs. Nenkirsch and Freytag, and is being rapidly adopted by German and foreign mining concerns, on account of its low-working expenses and simplicity of operation. It is true that the lower officials entrusted with the immediate superintendence of the process have to undergo a thorough training to account for the local conditions of the mine, but no skilled labor is required for the process itself.

The system is based on the use of cables carrying tempered-steel cutting points, the cables being driven by either one or two machines. The cutting machine represented in the accompanying illustrations is 36 in. in height, 40 in. in width and 8 ft. 4 in. in length, its capacity being 11.5 h.p. It is designed for electrical operation, but is readily adapted to compressed-air operation by some slight alterations in its construction.

The arrangement used in the case of electrical operation is represented in Figs. 1 and 2, and the one adapted to compressed-air operation in Figs. 3 and 4; general views of the electrically-operated machine are given in Figs. 5 and 6. These machines are from 1000 to 1500 lb. in weight, according to their size and type.

THE CUTTING MACHINE

The cutting machine mainly consists of a double-groove winch with automatic tightening gear. The wooden sheaves, which are generally arranged vertically, may also be installed in a horizontal direction below the machine, if this be more in agreement with local conditions. The tightening gear will carry the machine forward while forcing the cutting cable against the coal seam, but the pulling power of the machine is never exceeded. When the cable reaches any harder coal or rock, the speed of the tightening gear is slackened in proportion.

The machine comprises a base frame, on which are mounted the motor, toothed-wheel gearing and shafts of the wooden cable sheaves. The driving sheave is provided with two grooves and is about 32 in. in diameter, while the opposite wooden sheave, which has only one groove, is not driven.

The cutting cable, after passing over one of the grooves of the double sheave, goes on to the opposite single sheave and back again to the second groove of the driving sheave. The cable travels at a

speed of 5 ft. 8 in. per sec., or about 340 ft. per minute.

DESIGN OF CABLE

As regards the cutting cable itself (Fig. 7), this, in the case of small-size machines, is $\frac{3}{8}$ in. in thickness. The following varieties of cable, selected after several years' experiments, are used:

1. Cables made of triangular steel wire or wound with a sheath of such material. As this wire is braided, it obviously cannot be of hard steel. Such cables are of relatively high cost and are used only in the case of soft coal.

advantage of this design is that the edges are too easily bent down again. These caps can also be designed as files, and another process consists in braiding the steel points with the wire, according to the spiral lines of the latter, so as to work from all sides of the cut as they advance. The type of cutting tool represented in Fig. 7 is the one preferably used.

Next as regards the cutting process itself, three varieties should be distinguished:

1. *The revolving cable process*, according to which the cable, lined throughout its length with knives or other cutting

7. "

The Engineering & Mining Journal, N. Y.

2. Another type of cable is fitted with two steel caps $\frac{1}{8}$ in. thick and about $2\frac{1}{2}$ in. long. Each cap has eight holes, into which triangular points of high-class tempered tool steel are inserted. These cutting points are prevented from falling through the holes or getting forced into the cable by a thin piece of steel sheet, which is placed between them and the cable (Fig. 7). The two caps are fastened to the cable by two rivets, which part the strands of the latter. There is said to be absolutely no slipping of these cutting parts, which are placed on the cable at about 2-ft. intervals.

In another type of cutting cable these caps have slots, the edges of which are bent up and tempered. However, a dis-

tools, is made to turn around the pillar of coal.

2. *The reciprocating cable process.* The same machine, as above described, can be used in connection with this process, but there is a special switching device which has to be regularly adjusted. This adjustment can, of course, be made automatic. In the case of this process, only a small portion of the cutting cable, viz., that coming into contact with the coal seam, need be lined with cutting tools.

3. *A process consisting in making two separate cuts* (at the top and bottom of the pillar, respectively). This double process will be necessary only in the event of the coal being particularly hard, so that it does not break loose and fall down of

*Engineer, Berlin, W. 50, Tegensburgerstr. 3.

its own accord if a cut is made only at the bottom, or if the hole swells. Two small machines, arranged in each of the parallel passages, respectively, are preferably used in connection with this process. While Jeffrey machines can be converted with a view to their being used in this connection, this conversion will be worth while only in order not to shut them down entirely. However, the original Neukirch-Vreytag machine has been found far more practical and economical in operation.

or cables run, that is, at the top and bottom. On the other sides of the pillar, guide rollers should be provided. In connection with revolving cables, wooden rollers are preferable, but for reciprocating cables iron rollers are found more suitable.

In the case of the revolving-cable process, the machine should be adjusted toward the lower part, so that the cable may have a tendency to remain near the ground, if the bed of coal be inclined at an angle. If, on the contrary, the ma-

chine produce any noise nor raise any dust, while all blasting work is dispensed with. The wear and tear of the machine is far less than in the case of other constructions, the revolving parts of it being free from any coal-fragment impurities. Before proceeding to the final stroke, any other work can be carried out without interfering with the cutting process. Again, there is no interruption in the cutting work during the removal of the coal, and finally, the process allows any hard rock to be rapidly cut through.

CAPACITY OF MACHINE

As regards the capacity of the machine, 172 sq. ft. of coal have been cut, according to testimonials of the Deutscher Kaiser mine, at Hamborn, in Germany, under rather unfavorable conditions. The coal there is of moderate hardness and a triangular cable was used in cutting. The type of cable lined with two steel points would obviously have given still better results.

Supposing the case of a quadrangular wall, 30 ft. in width and 90 ft. in length, a cutting cable of $2 \times 30 + 2 \times 90 = 240$ ft. in length would be required.

The output of the machine above described is 300 ft. per min., or 18,000 ft. per hour. The width of the 30-ft. wall to be cut would accordingly be dealt with by the cutting points 600 times within its width. Supposing the cable to penetrate only $\frac{1}{4}$ in. on passing over moderately hard coal, it would have penetrated to a depth of 6 ft. 3 in. in one hour, which, in the case of a 30-ft. width, would mean an area of about 187 square feet.

It may be said that these figures are by no means exaggerated, outputs of the same area of magnitude having also been obtained in the Zwickau district. However, on the basis of only 172 sq. ft. per hour, as in the case of the Deutscher Kaiser, a cut of about 1080 sq. ft. would still be obtained for each shift, even in the most unfavorable of cases and allowing for any possible stoppage.

If the coal wall be 4 ft. 10 in. in thickness, a coal volume of 5300 cu. ft. would be obtained, which, supposing 1 cu. ft. to correspond to a weight of 60 lb., would result in 150 English tons per shift.

A maximum of three men is required to operate the machine. In order to utilize the machine to the best advantage, it would have to be installed in such a way as to allow one wall to its right, and a similar one to its left, to be prepared and to be surrounded with a cutting cable. If, then, the working of the right-hand wall for some reason or other should have to be temporarily discontinued, the cable of the other (hand) wall will be applied in a minimum of time, thus immediately continuing the hewing work.

CABLE CUTTING IS LESS EXPENSIVE THAN BY CHAIN MACHINE

The wear and tear of cutting cables

6 Hand Wheel for Controlling Cable Tension	12	

FIG. 4. TOP VIEW OF COMPRESSED-AIR CUTTING MACHINE

The machine should be installed in a side passage where no winding is done. It runs on a track of rails. The tightening gear should be firmly attached at a proper distance, and, as above stated, serves to draw the machine along with it, as the cable penetrates more and more into the seam of coal.

The cutting cable, according to the above, should be applied to the grooved sheaves, and according as it is either revolving or reciprocating, should be arranged to fit the conditions of each case.

In order to provide for an adequate guiding of the cable, it is well to break it cut a little at the corners where the cable

chine be placed high, the cutting cable will be apt to climb.

ADVANTAGES OF THE SYSTEM

As regards the advantages claimed for this process, it should be stated that the machine, being installed out of the way of the haulers, never interferes with their work, nor is it ever exposed to any risk of being damaged or crushed by falling coal.

The amount of energy required to work the machine is far less than in the case of any other system, and the machine is far simpler in construction and cheaper in operation. Furthermore, it does not

lined with two steel tapes is far less than that of triangular cables, and the cost of wear for each ton of worked coal is thus quite immaterial. In fact, this item will be far smaller than the wear of wheel and chain machines, whose teeth, owing to the greater height of their cut, have to perform a far greater amount of work. For a similar reason, the power consumption in the case of cable cutting will be far less than when using wheel and chain machines.

According to the American practice in the working of walls, pillars are partly left. Now, the cutting process above described will also be found of excellent use in the case of this special method, which, of course, differs from the German practice.

The following data are derived from an original estimate in meters and in round figures, which, in order to avoid

sq.m. per shift (as it is, it will yield 30 to 40 per cent. more in the case of an adequate use), four shifts of three men each will be required for this treble hewing, amounting to 12 shifts at \$4 each, or a total cost of \$48. The wages to be paid in working the rooms (above described) will, accordingly, amount to \$80. Even in case the foot-wall had to be cut, the outlay will never exceed \$100.

According to present coal-cutting methods, using other types of machines, wages would work out as follows: Each room contains $30 \times 10 \times 1.50 = 450$ cu.m. of minable coal at 1.5 tons each, that is, 675 tons. According to American data, the performance of each workman would be 6 to 10 tons, or an average of 8 tons each.

An aggregate of 84 shifts $\left(\frac{675}{8}\right)$ at \$4 each would, accordingly, be required,

Proceedings of the Mine Inspectors' Institute

SPECIAL CORRESPONDENCE

The second annual convention of the Mine Inspectors' Institute opened on Tuesday afternoon in Scranton, Penn., there being about 50 mine inspectors from various parts of the country present, many of them having come long distances at their own expense to attend the convention, and one at least coming 2000 miles.

The president of the convention, George Harrison, chief mine inspector of Ohio, in his opening address to the convention explained the object for which the institute was founded a year ago. He said that while the mine inspectors were without an organization, anything like concerted

FIG. 5. GENERAL VIEW OF ELECTRICALLY-OPERATED MACHINE

FIG. 6. SIDE VIEW OF MACHINE WEIGHING LESS THAN 1500 POUNDS

any complication, have not been converted into their English equivalents.

THE COST OF CUTTING

Supposing the "room" to be hewn is 30 m. in length and 10 m. in width, the coal reaching to a height of 1.5 m.; one hole (from one way to the other) would have to be bored at each of the four corners, and these holes will presumably be completed by two men in two shifts. However, for this operation, allowing a time twice as long, that is, $2 \times 4 = 8$ shifts at \$4 each, this will figure up to a total cost of \$32. Some workmen should be trained for the special work of boring such holes, and these men will always have to be in advance with their work.

The process of cutting these "rooms" will then be as follows:

After passing the cable through the upper and lower holes, the coal should at first be cut in a vertical direction, after which the bottom of the foot-wall, and eventually the other side, should be cut vertically. The two vertical cuts will result in $2 \times 30 \times 1.50 = 90$ sq.m., and the cut on the foot wall is $30 \times 10 = 300$ sq.m., working out at an aggregate of 390 sq.m. If this machine be able to cut 100

FIG. 7. GENERAL VIEW OF CUTTING CABLE

amounting to \$330 in wages, that is, to \$200 in excess of the amount corresponding to the novel method here described.

Calcium chloride is a grayish-white substance, which has the power of strongly attracting moisture from the atmosphere, and of holding same. When used to dampen dust on coal-mine roads, it contains nothing that can be injurious to the miner, roadways, haulage-ropes, etc. It does not give off any smell or gas. Comparing its hygroscopic property with salt, salt of itself has not the power of attracting moisture, but owes what little power it does possess to a small amount of impurity which it contains in the form of magnesium chloride, and cannot be for one moment compared with calcium chloride, as a moisture-attracting substance.

action was impossible. The loss of life, the speaker said, had increased and was increasing in the mines, in many instances, at least, without justifiable cause. This was so not in one mining State or two, but throughout all the States in which coal measures were found. Now the object which the Mine Inspectors' Institute had placed before them, and which they would try to realize, was to minimize the loss of life in the mines by minimizing the dangers of mining as far as they could effect it. How was that to be accomplished? According to the speaker, this could in a considerable degree at least be effected by an interchange of ideas among the mine inspectors. This interchange of ideas could be conducted only through an organization such as they had founded 12 months ago at Indianapolis. At that convention there were 45 mine inspectors, but since that time the membership of the Institute had considerably increased, and with the increase of numbers came an increase of influence in each State and throughout the United States.

One of the results of their Indianapolis convention was the foundation of the testing station at Pittsburg, established by the United States Government at a cost of

\$150,000. They must strive to make not only the Federal Government interested in the safety of life in the mines, but they must try and make the State governments interested also. None of the State governments had so far erected experimental or testing stations, such as were common in the mining centers of Europe. They must also, he said, interest the large operators in these matters to a greater extent than is the case now. That was their mission, and in brief, this was the manner in which they hoped to carry it out. He was disappointed at the failure of the bill in Congress to establish a bureau of mines and testing stations.

After the president's address the convention went into session, and for the greater part of the evening was occupied with the selection of committees and other routine matters.

The following committees were appointed: Executive committee, H. D. Johnson, Pennsylvania; Peter Honratty, Oklahoma; Albert A. Sams, Indiana. Committee on constitution, John Verner, Iowa; W. H. Turner, Ohio; Thomas Moses, Illinois. Committee on resolutions, Thomas K. Adams, Pennsylvania; P. A. Grady, West Virginia; Thomas Hudson, Illinois. Membership committee, Clarence Hall, District of Columbia; J. T. Beard, Pennsylvania; J. L. McDonald, Ohio.

In the evening a social and smoker was given, but so far from the affair being preoccupied with merely musical or social functions, on the contrary, it was technically most interesting, four important addresses on mining matters being delivered, as well as an address of welcome by Judge H. M. Edwards, of Lackawanna county, in the absence of the Mayor of Scranton.

President Harrison delivered a second address, in which, after reiterating the purpose for which the meeting was called, the purpose for which the Institute was formed, and a few allusions to the welcome which the city of Scranton had extended to the delegates, he plunged into the duties of mine inspectors and the conditions that lead to the loss of life in the mines. He declared that the time had come when miners and operators must lay aside their bickerings and disagreements and work in concert for the good of all who were employed in the mines, or who drew a revenue from them. He asserted that 55 years ago when he first became a working miner, the miner took pride in his employment; that he kept his chamber clean; that he never blasted coal unless he had first cut each side of the block of coal that he intended to bring down and made a clean cut underneath. "But mining at the present day," said the speaker, "is a lost art." Take any "Tom, Dick, or Harry," place a keg of powder under one arm and a large auger under the other, and let him become a member of the United Mine Workers' Union, and you have a full-fledged miner, and a

dangerous one to himself and all his fellow workers.

A CURRENT OF 500 VOLTS IS DANGEROUS

The speaker called attention to blasting, and particularly to the new conditions involved in working the mines with electricity. He deprecated the use of high-voltage electrical currents, and declared that many of the fatal accidents in the mines were due to this cause. A voltage of 250 was said to be fairly safe, but when it was raised to 500 there was no such safety, and furthermore, the amount of coal that could be cut by doubling the voltage was only 10 per cent. more, as a general rule. The operators were indifferent, Mr. Harrison said, because they thought that by higher voltage there was more expedition, and the coal cut was as good. Mr. Harrison said that he did not believe in insulated wires; owing to the minerals in the water, dampness and one thing or another, the insulation became both defective and deceptive. When a miner took hold of a wire that was supposed to be insulated, but which was not so in fact, a fatal accident occurred. He also said that more care should be taken in installing electric wires, which were sometimes strung anywhere and anyhow as if they were so many hemp ropes.

J. H. Taylor, of Illinois, in the course of a somewhat lengthy and discursive address, warned the inspectors to beware of what he called the "theoretical fellow;" he also advocated the employment of the acetylene lamp in the mines, which, he declared, burned clearly and brightly when the ventilation of the mine itself was dangerous to human life, and that oxygen was not so essential to the illumination of the acetylene lamp.

J. H. Holmes, of the United States Geological Survey, in the opening of his address said that he had heard that morning that there was an undertakers' convention also being held in Scranton, and that he hoped, although the undertakers of the country had about 1000 fewer mineworkers last year to lay underground than they had during the preceding year, that the conventions would not be the less friendly, as both were underground diggers. Reverting to the warning given by Inspector Taylor to beware of the "theoretical fellow," Doctor Holmes said that theory and practice in any effective undertaking usually went together. For instance, in the Government testing station at Pittsburg, those in charge had invited the manufacturers of explosives to send in samples of their products which would be tested, secretly, under their own eyes, without fuss or feathers. If the explosive survived the Government test, the name of the manufacturer would be published; that is, the name would be printed in the circulars distributed by the testing station. If the product did not come up to the standard, nothing would be said about it, the name of the manufacturer would not

be printed, but he would be requested to withdraw the product from sale, or to bring it up to the standard of safety. The same course was pursued in regard to electrical appliances used in the mines. These, too, were tested under similar conditions.

Doctor Holmes also said that a report had obtained circulation among mine inspectors that the Federal Government was about to undertake the inspection of mines. There was not a word of truth in this. The Government had no such intention. The only object of the Government in establishing the testing station was to aid the State mining inspectors in every way it could. Doctor Holmes, in conclusion, deprecated the present cut-throat competition among operators, and thought that the conditions at the mines would never be improved as they should be until the mineowners charged an adequate price for the coal at the mouth of the mine, as they do in England, where the operators receive \$1.60 per ton, on an average, instead of 60c. paid here.

A New Potash Salt

Although it has long been admitted that the red color of carnallite is due to iron oxide from the decomposition of some earlier ferruginous potash salt, it is only quite recently that a salt of this kind has been discovered. This discovery was made by Mr. Boeke in the mines of the Nordhäuser Kaliwerke, at a depth of 547 m., where the hard salt rests on the carnallite, in association with sylvine. The new salt, according to *Vulkan*, April 21, 1909, is of a pale pink or violet color in the bed, but turns yellow within a very few minutes after removal. It is very hard, with splintery fracture, the splinters being hard enough to wound the finger; it exhibits a characteristic inky taste. On exposure to the air it crumbles down to a sandy powder, the presence of which in the salt has led to shipments being rejected as "adulterated with sand," although the "sand" contains 50 per cent. of potassium chloride. In composition it consists of one part ferrous chloride, three parts potassium chloride, and one part sodium chloride, chemically combined, and is anhydrous. It has been named rinneite, after Professor Rinne, formerly of the Hanover Technical High School.

The 1908 production of alum and aluminum sulphate decreased from the figures for 1907. As shown by statistics of the U. S. Geological Survey, the output for the respective years was: 1907, alum, 10,404 short tons, valued at \$34.78 per ton; aluminum sulphate, 106,821 short tons valued at \$18.80 per ton; 1908, alum, 7700 short tons at \$30.74 per ton and aluminum sulphate 97,255 short tons at \$18.87 per ton.

Time Recorder for Furnace Operations

By O. E. JAGER*

For the successful running of reverberatory furnaces it is sometimes necessary to keep track of the times of charging, tapping and skimming. If this is left to the furnaceman's memory it is liable to be reported wrongly or forgotten altogether. To overcome this difficulty I have devised the following arrangement of a Bristol recording gage:

Take any Bristol recording gage (the kind is immaterial as it becomes merely a

been done in the tinshop, the words, "skim," "tap" and "charge" are painted above their respective slots. In the accompanying illustration the marks nearest the center of the chart represent skimming, those in the middle, tapping, and the outside mark, the time of charging. The duration of the operations is not recorded.

Fit the tinplate over the chart in the place of the glass, and the apparatus is complete. The scribe can be made of a hardwood-pen handle tapered down to a long fine point. Use a No. 350 Bristol patent-smoked chart, which can be "fixed," after using, by immersion in a very weak solution of shellac in wood alcohol, thus

South African Diamond Mines

SPECIAL CORRESPONDENCE

At the recent annual meeting of the Premier Diamond Mining Company, managing director, Ross Frames, delivered a vigorous, fighting speech which thoroughly upheld the "traditions" of this young concern. The boldness of his views and the bitterness of his criticism of the De Beer's policy would have made more satisfactory reading to shareholders and public if the point of the question calling for solution were only the relation between the Premier's actual or prospective production and that of De Beers; for the managing director made out a good case for the Transvaal mine's claim to contribute a high proportion of the total yield. But the relation between its production and the market demand was discussed with less assurance and detail. The tone adopted in regard to this important point was one of unexpected confidence. Mr. Frames could not, of course, deny the reality of the market's collapse, but he contended that it had been greatly exaggerated.

The speeches of W. F. Frames and of Mr. Cullinan (chairman) were largely composed of criticisms in reply to the recent pronouncements of the chairman of De Beers. Apart from the points of debate, a great deal of valuable information was given as to mining conditions and results. The opinion was expressed with conviction that the Premier mine has now reached its "permanent" grade—that the present yield of about 25 to 26 carats per 100 loads (of 16 cub. ft. each) will probably see small variations in the future. Extensive tests of blue ground have shown average contents of 26 carats. It is reported that a layer of comparatively soft blue ground has been proved below the present workings, and that 45,000,000 loads of this material can be considered to be "in sight." It is well known that the Premier turns out a large quantity of inferior diamonds. Mr. Cullinan gave some interesting figures in evidence of this fact by stating that 33 per cent. in weight of the output represented 70 per cent. of the value. While the yield per 100 loads has been steadily decreasing to the present figure of 25.5 carats, the increasing scale and efficiency of operations has enabled working costs to be reduced to nearly 36c. per load. In the first year of high yields, the cost per carat was \$1.72; later on, when the whole mine was worked and yields fell, it went up to \$3.22 per carat. Now the cost has again dropped to \$1.72 per carat.

The directors appear to have found themselves resolutely to a policy of expansion, in spite of all dangers of overproduction. The Premier produced 2,078,825 carats of diamonds last year. When the new No. 4 gear is completed, the

The Engineering & Mining Journal, N.Y.

RECORDING REVERBERATORY-FURNACE OPERATIONS AT THE STEPTOE SMELTER

time recorder in this instance), remove the front glass and turn the pen away to one side. Take a sheet of stout tinplate and cut it to the same size as the glass (8 5/16 in. in diameter for a gage taking 8-in. charts). Mark three slots, as shown on the record, on the same radius as the time lines on the chart. As the glass sets away from the chart about 3/4 in., the slots must be made with all sides sloping inward toward the chart, leaving about 1/16 in. clearance between the tin and the chart, so as to insure the correct marking of time by the scribe. This job having

constituting a record of operations for the day ready for filing.

The gage is put up in any convenient place near the furnace, and the scribe hung to it by a piece of string. Set the chart with the correct time directly under the slot. After skimming, tapping or charging, the furnaceman simply takes the scribe and marks in the corresponding slot. The fact of the gage being there is a reminder to him to do this. At the end of each shift the foreman opens the gage and copies off the times of the respective operations on his report. The chart can be easily modified to suit other operations.

*McGill, Nev.

company will be treating 50,000 loads per day or, say, 16,000,000 loads per year. This, at 25 carats per 100 loads, is equivalent to 4,000,000 carats per annum. As announced by Mr. Cullinan, 67 per cent. of the yield by weight represents only 30 per cent. of the value. He further declared that only 12½ per cent. of the output in money value (presumably 30 or 40 per cent. by weight) need be regarded as in the least difficult of sale, when larger quantities are produced than at present.

The chairman gave some interesting statistics regarding the records of the Premier from the commencement of operations in 1902. Excluding the Cullinan diamond, the yield to date is valued at £6,500,000, of which £3,700,000 represents profit. On equipment £1,413,666 has been spent, £1,009,076 has been paid to the Government in profit tax and £880,000 distributed in dividends.

Useful Formulas

By F. CLOSE*

In the course of my experience, I have encountered or worked out, for my own convenience, various useful formulas calculated to save time, and have embodied the most useful of them in this paper in the hope that it will be added to from the experience of others. Most metallurgists and engineers have their own particular methods of working out problems which occur constantly in chemistry, surveying, etc., and a collection of the experiences thus gained should prove valuable.

One of the most useful formulas is that for the calculation of extractions.

Let assay of original = O_a .
Weight of original = O_w .
Assay of tailings = T_a .
Weight of tailings = T_w .
Assay of concentrates = C_a .
Weight of concentrates = C_w .

Then the percentage extraction may be calculated from the weight and assay of concentrates; thus "concentrates products accounted for" or

$$\text{recovery} = \frac{C_a \times C_w}{O_a \times O_w} \times 100.$$

Similarly, "tailings products accounted for" or

$$\text{loss} = \frac{T_a \times T_w}{O_a \times O_w} \times 100.$$

Obviously the "extraction calculated from tailings" is 100 minus the above result. Examples of calculation of recovery by these formulas follow.

Let.

$O_a = 15$ per cent. Zn and 12 oz. Ag per ton.

$O_w = 120$ ton.

$T_a = 7.5$ per cent. Zn and 3 oz. Ag per ton.

$T_w = 96$ tons.

$C_a = 45$ per cent. Zn and 48 oz. Ag per ton.

$C_w = 24$ tons.

Extraction of zinc calculated from weight and assay of concentrates would be

$$\frac{45 \times 24}{15 \times 120} \times 100 = 60$$

per cent. recovery.

Extraction of silver calculated from weight and assay of concentrates is

$$\frac{24 \times 48}{120 \times 12} \times 100 = 80$$

per cent. recovery.

Zinc tailings products accounted for:

$$\frac{7.5 \times 96}{15 \times 120} \times 100 = 40$$

per cent.

The extraction calculated from tailings is 100—40, or 60 per cent. recovered in concentrates, by difference.

The silver tailings products accounted for are:

$$\frac{3 \times 96}{12 \times 120} \times 100 = 20$$

per cent.

The extraction calculated from tailings is 100—20, or 80 per cent. recovery in concentrates.

A formula may now easily be derived for the calculation of extractions when only the assays of the products are known, the weights being unknown. The weight of the concentrates in terms of percentage by weight of the original may be expressed thus:

Percentage weight of concentrates =

$$\frac{O_a - T_a}{C_a - T_a} \times 100.$$

$$\text{Extraction} = \frac{C_a}{O_a} \times$$

percentage weight of concentrates.

Combining these last two formulas, the full formula for calculating the extraction is

$$\frac{C_a}{O_a} \times \frac{O_a - T_a}{C_a - T_a} \times 100.$$

Working out the above example from this formula, we have for the zinc extraction

$$\frac{45}{15} \times \frac{15 - 7.5}{45 - 7.5} \times 100 = 60$$

per cent

The silver recovery would be

$$\frac{48}{12} \times \frac{12 - 3}{48 - 3} \times 100 = 80$$

per cent

the method of arriving at the final

formula may be readily reviewed at any time by examining the formulas which have been combined to obtain the extraction formula. It will be noted that the extraction thus calculated without the weights works out the same as the extraction calculated from weight and assay, namely 60 per cent. for Zn, and 80 per cent. for Ag. Owing to errors in sampling or assaying, the extractions and weights worked out by formula will seldom check as closely in actual practice as in the above examples. A combination of errors may be either cumulative or neutralizing in effect. It should be noted that a + error, causing a + deviation from the correct result calculated by weight and assay, causes a — deviation calculated from the formula using assays only, and *vice versa*. This is apparently contradictory, but in the case of a + error in tails, calculated from weight and assay, the error must be added to the "tailings products accounted for," and the result subtracted from 100 to get the "extraction calculated from tailings," thus lowering the extraction. When calculating by the assay formula the same + error in tails assay will cause a — deviation from the correct result and this — quantity must be subtracted to get the correct extraction.

The following formulas for the rapid calculation of the quantity of water contained in pipes may be found useful:

$$\frac{(\text{Diameter in inches})^3}{5} =$$

Imp. gallons in 6 ft. of pipe, or

$$(\text{Diameter in inches})^3 \times 2 =$$

pounds of water in 6 ft. of pipe.

As an example, suppose one desires to know roughly how much water is contained in a 6-in. pipe, 12 ft. long.

$$\frac{36}{5} \times 2 = 14.4$$

Imp. gallons, or

$$36 \times 2 \times 2 = 144$$

pounds.

This is an approximation only, the correct figure being 147 lb. The 2 per cent. error can, however, in most cases, be neglected. Given the diameter of the plunger and the stroke, the amount of water delivered by a plunger pump per stroke can be quickly calculated from this formula.

The annual report of the German ammonia trust (*Chem. Trade Journ.*, April 17, 1909) gives the European and American production of sulphate of ammonia as follows: Great Britain, about 314,000 tons; Germany, 313,000; United States, 82,000; France, 54,000; Belgium and Holland, 35,000; Austria, Spain and other countries, 80,000 tons.

Pensions for Iron Miners

The Cleveland Cliffs Iron Company, of Michigan, has established a system for pensioning its employees who have been disabled by accident or through age and long service. Besides allowing pensions for retired employes, the widows and orphans of workmen killed while discharging their duty are also to be benefited. One provision is that the widow and children of the workman meeting death must be residents of the United States at the time of the fatality. If a man accidentally killed while at work for the company leaves a widow without children, or a widow with children under the age of 16 years who are dependent upon their own efforts for support, or if he leaves children under the age of 16 who are without other means of support, but leaves no widow, the company will contribute \$12 per month to her or their support for a period of five years. If the widow should marry or become self supporting within that time the pension will cease. For each child under 16 years of age left with a widowed mother, \$1 per month in addition to the \$12 allowed her will be paid for a period of five years. If there is no widow the children under 16 years of age will receive their allowance through an administrator. In the event that all children of employees meeting death at the company's properties are under 10 years of age the pension board will have the power to extend payments beyond the five-year period.

Under the rules to govern the payment of pensions no assignments of money due widows or orphans will be accepted, nor will the company recognize such assignments in any way. No money due, or about to become due, a pensioner will be liable to attachment, levy or seizure by or under any legal process whatever, whether the same remains with the company or an agent thereof. Should a creditor attempt to collect moneys due a pensioner, such pension allowance shall be forfeited to the company and shall belong to it absolutely, to be dealt with as the pension board shall deem proper.

All pension allowances will be paid monthly during the life of the beneficiary, but the company may withhold its stipend in case of gross misconduct.

All employees who have attained the age of 70 years and have been in the service of the company for 20 years or more, the last 10 of which shall have been continuous, shall be retired and pensioned.

Any employee who has attained the age of 60 to 69, and who has been in the service of the company 25 years or more, the last 10 of which shall have been continuous, may at his own request be retired from active service and become eligible to a pension.

The monthly allowance paid each person shall be on the following basis:

For each year of service 1 per cent. of the average monthly pay for the 10 years next preceding retirement, provided that the annual pension disbursements for all persons shall not exceed the amount available from the pension fund, set aside by the pension board.

Should the aggregate pension allowance for two successive years exceed the amount added for those two years to the pension fund through apportionment and interest, in the absence of action by the board of directors a new rate shall be established by the pension board proportionally reducing all allowances. Notice of change of rate shall be given employees who are on the pension roll before the beginning of the fiscal year in which the change shall become effective.

The amount of pensions will depend, as above stated, upon two conditions: the number of years an employee has served the company, and the amount of his average wages per month, for the 10 years preceding retirement. If the average earnings, as above, should exceed \$100 per month, the pension payment will be based on \$10, this being the maximum wage on which pension allowance will be computed; but no pension shall be less than \$15 per month.

The pension board will be composed of W. G. Mather, M. M. Duncan, Austin Farrell, C. V. R. Townsend, W. P. Belden and W. H. Moulton. Mr. Mather is president and Mr Moulton is the board's secretary.

In 1908 the United States produced 15 tons of molybdenum ore worth approximately \$6000 according to statistics of THE MINERAL INDUSTRY

Drying Air for Blast Furnaces

F. W. Harbord describes (British Pat. 4424 of 1908) an apparatus for removing moisture from the air before it enters blast furnaces used for the manufacture of iron. In his specification 25,112 of 1906 various materials, as salts in connection with absorbing agents such as coke, kieselguhr, etc., were suggested and in his later specification, dried peat. With the latter the use of two or more chambers alternately was proposed, but now the hydrated material is not only first dried, but it is also cooled prior to being hydrated again.

In the accompanying illustration is shown a sectional elevation of a chamber in which are bricks of peat *G* and lumps *H*, all of which have been saturated with calcium and ferric chloride and afterward dried. The valves *B*, *C* and *E* being closed the air from the subsidiary blower enters *A*, and passes through the dehydrating chamber, the dry air leaving the chamber through the valve *D*.

When the dehydrating material is so saturated with moisture that it fails to work effectively, valves *A* and *D* are closed while valves *B* and *C* are opened and hot air at about 210 deg. C., is drawn or forced through the material to dry it, and through valve *E* hot air or gas enters the surrounding jacket. Meantime the moist air from the blower passes through the second cooled chamber, and then through the third chamber in which the material has just been dried and which it is desired to cool.

Mercury in Italy

According to a report by Mr. Nicou, the columnar deposits of cinnabar in the Monte Amiata district contain 1 per cent. mineral (60 per cent. mercury) (*La Metallurgie*, April 21, 1909). The ore is screened, and all the small fragments less than 1½ in. are roasted in Cermak furnaces. The chief mine is that of Abbadia San Salvatore, which turns out about 25,000 tons of 1-per cent. ore yearly. Altogether, the number of furnaces running is 28, among which are seven Cermak furnaces with a capacity of 24 to 30 tons, four of 12 to 15 tons' capacity, four of 2 to 8 tons' capacity, and 13 ordinary 6-ton furnaces. The average recovery from a large furnace is 95.2 per cent. of the total mercury contained in the ore. The latter costs 13s. 6d. to 22s. 6d. per ton at the mine, and the cost of classification, conveyance, and treatment is 3s. 3d. per ton, making the total cost 16s. 9d. to 25s. 9d. for the 123½ lb. of mercury recovered, or 1s. 4d. to 2s. per lb. Although the quality of the ore is diminishing, the use of improved appliances enables the output of mercury to be maintained, and even increased, so that Italy contributes nearly 400 tons out of a total of about 3600 tons produced throughout the world.

Crucible Assays

By A. A. STEEL*

When first teaching a class in assaying, I was impressed by the vague and unscientific discussions of crucible charges as given in all the older text books. Most of these simply give tables of charges for various pure gangues, and it is difficult from these to flux mixtures of minerals. A method of figuring crucible charges was therefore worked out so as to eliminate all uncertainties except the exact percentage composition of the gangue.

Professor Fulton's recent book¹ has a good discussion of the nature of assay slags but it gives no simple method of figuring charges. It may be of interest therefore to present the following directions for crucible assaying, which are given to the students of the University of Arkansas after they have figured a few slags by metallurgical methods:

DIRECTIONS FOR FLUXING CHARGES

(1) Examine the material submitted for assay and estimate its approximate mineralogical composition. Then write down the corresponding weight of each mineral in the quantity to be melted (usually 0.5 A.T., called 15 grams.)

(2) *Silica.* Add, if necessary, enough silica to make with that already present in the ore 2 grams of SiO_2 for each gram of CaCO_3 , MgCO_3 or BaSO_4 (calcite, dolomite or barite) present, and $1\frac{1}{2}$ grams for each gram of Fe_2O_3 , ZnO , clay or other infusible silicate (hematite, zinc mineral, kaolin, etc. Limonite is equivalent to $\frac{7}{8}$ its weight Fe_2O_3 and pyrite to $\frac{3}{8}$.) Consider $1\frac{1}{4}$ grams of powdered glass equivalent to one gram of silica.

(3) *Borax.* Add $\frac{1}{2}$ of a gram of borax glass for each gram of silica or infusible silicate (clay or talc) present in the ore and the fluxes. For cupel assays add four grams of borax for each gram of bone ash.

(4) *Soda.* Add $1\frac{1}{3}$ grams of sodium bicarbonate for each gram of SiO_2 present in the ore or fluxes. Consider fusible silicates as glass, etc., equivalent to 50 per cent. silica. For pure lead ores add at least $\frac{2}{3}$ the weight of the ore. For clay, talc, etc., use a mixture of soda and potash.

(5) *Litharge.* Add enough litharge (0–20 grams) to make with the lead already in the ore an 18-gram button and in addition for the slag, 2 grams of PbO for each gram of silica or infusible silicate in the ore. (Consider glass as equivalent to 50 per cent. silica.) For cupels add 2 grams of PbO for each gram of bone ash. Increase the amount of PbO largely to keep copper, zinc, antimony, arsenic,

and tellurium out of the button if they are present in the ore. For ease in correction for silver in the PbO use litharge in even multiples of 10 grams only.

(6) *Argol or niter.* Add enough argol or niter to make an 18-gram button. One gram of Fe_2O_3 may be assumed to prevent the reduction of about $1\frac{1}{2}$ grams of lead, but the reducing power of sulphides should be determined by a preliminary assay if they are present. When more niter, than the weight of the ore is required do not use this method. Roast ores containing much pyrite, antimony or arsenic adding charcoal for antimony and arsenic. If but little niter is required use the niter method in preference to roasting. For galena, etc., nails may be used with charges in which the PbO for the slag is replaced by NaHCO_3 in excess. When niter is added in the nail method, be careful to form no FeO which will not fuse in the soda slag.

(7) Buttons brittle from antimony or zinc or showing scales of copper must be scorified.

This system of fluxing forms a bisilicate of Na_2O and PbO or $\text{Na}_2\text{Pb}(\text{SiO}_3)_2$. This is ample flux for a pure quartz gangue and in it the other bases dissolve forming, of course, slags of lower silicate degree. As given, the charge for pure limestone yields a slag of oxygen ratio of 1 in the base to 1.54 in the acid not counting borax. BaSO_4 gives a ratio of 1 to 1.7; MgCO_3 , 1 to 1.47; Fe_2O_3 (as FeO), 1 to 1.33; clay, 1 to 1.42; etc.

EFFECT OF THE BORAX

Since borax is added to form a borosilicate it is reasonable to figure it according to the amount of SiO_2 present in the slag. The proportion given has not been finally settled upon as the best. It is sufficient to greatly lower the temperature of slag formation, to make the slag viscous during the reduction period, and to lower the temperature of final complete fluidity. It is also sufficient to serve as a general safeguard to flux a slight excess of either acid or base. On the other hand it is expensive and makes the buttons more difficult to clean.

Our charges are a little higher in PbO than usual and for some basic ores it will be more economical to substitute soda for litharge but this makes the charge more bulky. For ease in remembering it was thought better to have a constant ratio of soda and litharge to silica rather than to use the form 1 to $1\frac{1}{2}$ grams of soda and 1.5 to 2 grams of PbO for each gram of silica, which is more nearly what would be used by an experienced assayer.

The amount of fluxes as given by this table are ample and without any great excess. In estimating weights to be fluxed even grams are taken, using care to see that the weight of refractory mineral is over-estimated rather than under-estimated. The minimum amount of the soda-lead silicate required to dissolve

the various bases has not yet been accurately determined. If I ever conduct a class in assaying again, this will be worked out for the more common minerals by making up charges of the pure oxides, etc. It is also desired to work out the amount of excess litharge needed for each gram of copper, antimony, etc., in the charge to make clean buttons. This PbO method has been found to work well with up to 25 per cent. of antimony and 60 per cent. of zinc as sulphides but is not so successful for copper.

DISSOLVING ACTION OF LITHARGE

A large excess of PbO severely attacks the crucibles and the risk of ruining the muffle by spilled charges becomes important. Therefore it is thought best to scorify the coppery buttons as is done with the buttons obtained in the standard scorification method for copper mattes.

On account of this dissolving action of litharge upon the crucibles more litharge, as given in the directions, is of advantage in assaying clay and talc ores. The charges without excess litharge have very little effect upon Denver crucibles and attack the Battersea crucibles but slightly. The borax seems to protect the crucibles from being drilled by PbO probably by coating them with a viscous aluminum borosilicate.

We have found that by long fusion cupels can be entirely dissolved to a fairly fluid slag by much borax with some PbO and no soda or silica. This forms calcium borate and sodium phosphate as in the tests on platinum wire. The amount of bone ash in the charge is determined by weighing the cupel with the litharge and subtracting the standard weight of that size cupel when new, to give the PbO to be deducted from the weight of the stained part of the cupel. Apology is asked for the incomplete state of these data, but I thought it better to publish this now, rather than postpone it indefinitely in awaiting complete data.

Probably the best time ever made in loading iron ore in the Lake Superior region was made by the "W. E. Corey," a Steel Corporation boat, at Ashland, Wis., on June 8. The vessel sailed with 10,234 tons of iron ore on board in 83 minutes from the time she tied up at the dock light. The actual loading time was 63 minutes, making an average of 150 tons per minute.

Discoveries of copper, gold and silver are reported to have been made on the Fiji islands, and western Australian mining men are at Suva, Viti Levu, awaiting the gazette by the local government of regulations under which mining may be carried on, after which the new finds will be thoroughly exploited. No mining on a commercial scale has ever been done on these islands.

Colliery Notes

The Ruhr coalfield in Germany is the largest and most important coalfield in that country. It covers an area of approximately 1080 sq.m. The estimated amount of available coal in Germany is 140,000,000,000 tons.

An average sample of Picton (Nova Scotia) coal shows the following composition: Fixed carbon, 61.95; volatile matter, 25.87; moisture, 1.75; ash, 10.42. From this variety of coal 8000 cu.ft. of 15 c.-p. gas can be produced.

Many mining engineers are advising against the use of electrical coal cutters at the faces of gaseous workings. They claim it is better to install compressors in places where electricity may be taken with comparative safety, and then work the cutters with compressed air.

Accidents in coal mines often result from unexpected causes. One such case recently occurred in an English mine where a stone fell from the roof and an armored cable was cut. The mine was gaseous and a spark from the cut cable fired the explosive mixture with fatal results.

England and the United States are the only two countries that produce such quantities of good fuel for all purposes as to render the importation of any further supply unnecessary. Germany, France, Belgium and Austria raise enormous quantities of fuel, but the coal measures of these latter countries are deficient in some varieties that are required for specific purposes.

It is usually true, except where conditions are modified by the percolation of water, that the quantity of firedamp given off in a mine, as well as the temperature and dryness of the underground workings, increases proportionately with depth. It will generally be found that workings at a depth of from 500 to 700 ft. are damp in hot weather and dry in cold weather. Workings at a greater depth than 700 ft. are nearly always dry, and the deeper the drier.

When considering an electrical underground installation, the mine manager or superintendent should remember that although the danger of shock is a matter to be carefully considered, the greater problem should be to try and eliminate the dangers from fire and explosions of gas that may result from the use of electricity. One serious explosion is likely to cause a greater loss of life than would result from electric shocks during the period of a year.

Professor Galloway recently stated as his belief that the damping of the dust for a certain distance in front of blasting shots about to be fired should be compulsory. He does not approve of shirking this precaution on the plea that permitted

explosives are used. He regards it as obvious that if the deposition of coal dust in the roadways of mines could be altogether prevented, or failing that, if after being deposited it could be rendered innocuous, great explosions would become impossible.

In preventing the deposition of coal dust in the roadways of mines, Professor Galloway says that the only means of effecting this result is to make use of dust-tight mine cars, filled to the level of their upper edges with coal; then to convey these cars along the roadway at such a speed that the shaking to which their contents are subjected during transit, is insufficient to cause dust to arise from them; and to carefully gather up and remove all traces of coal from the floor when a car happens to be accidentally overturned.

It is difficult to estimate proportionately the classes of work to which coal is put, therefore the following figures of an English statistician are most interesting. This writer extended his research over a period of years and gives the percentages of the main applications of coal in the United Kingdom as follows: Railways, 8.19; coasting steamers, 4.81; collieries, 7.22; factories, 24.07; blast furnaces, 11.44; steel and malleable iron works, 7.85; other metallurgical works, 1.20; chemical works, potteries, glass works, 3.61; gas works, 9.63; domestic, 21.68.

It is still a debated question as to whether as good results in the blast furnace can be obtained with by-product as with beehive coke. After examining this problem, Charles Bell stated that with the same ore, the consumption of coke per ton of pig iron showed a saving of 2.29 cwt. in favor of the by-product article. Opinion is still divided, however, as to the relative merits of the two cokes for smelting purposes. With the improved type of modern by-product ovens the superiority, if any, of the beehive cokes is very slight, and is not sufficient to justify the wastage incidental to coking in the beehive oven.

Dry powdered calcium chloride, similar to the product used for damping dust in coal mines, is a rather expensive article, costing about \$12 a ton. As compared with the cost of sprinkling with plain water, the use of the powder shows a saving in labor, and does not require any capital outlay for pipes, barrels, hoses, sprinklers, etc. One mine manager estimates that the cost of sprinkling an entry, 9 ft. wide and 300 ft. long, with powdered calcium chloride, would average about \$3.12; the water would have to be applied daily, whereas the calcium chloride would apparently be effective for three months.

Professor Meyer, of Germany, who conducted a number of experiments to determine the nature and quantity of the gases occluded in various coals, placed pieces of coal of the size of a

nut in a flask and boiled them in water which had previously been made air-free by boiling; the flask was provided with an india-rubber stopper, through which a glass tube led the escaping gases. The latter were collected over boiling water. Professor Meyer obtained from British and Westphalian samples, heated to 100 deg. C., from 4 to 238 c.c. of gas per 100 grams of coal. The gases varied in composition, but all contained carburetted hydrogen, carbon dioxide, oxygen and nitrogen.

A large metal safety barrier was recently built for the Heinitz colliery, Upper Silesia. The barrier is constructed in three sections, and is designed to stand a pressure of 750 lb., and is provided with three doors; two of these doors measure 6 ft. in height by 3½ ft. wide, and are used for the passage of the cars in the haulage road; the middle door is for foot passengers, being 6 ft. high and 31 in. wide. The total weight of the barrier is 35 tons. The metal used in making the casting consisted of pig iron with an addition of steel, the resulting material being stronger and tougher than gray cast iron, and midway between the latter and cast steel in point of tensile strength, while cheaper than cast steel.

The total exposed area of the seven important coalfields of England and Wales, is 2786 sq.m. There are in the various fields 100 seams of coal of more than 2 ft. in thickness at a less depth than 4000 ft. These beds represent a total thickness of 666 ft., an average of about 3 ft. 6 in. per seam. According to a recent report by the Royal Coal Commission, the amount of fuel still available in the above areas, excluding all seams of less than 2 ft. in thickness and more than 4000 ft. deep, is 79,000,000,000 tons. The thinner and deeper seams are estimated to contain an additional 70,000,000,000 tons. According to this estimate, and basing calculations on the present annual rate of extraction, the combined coal resources of Great Britain should last about 600 years.

China is rich in coal, which is widely distributed throughout the vast empire. The coal measures are of an age more recent than the Carboniferous, probably Jurassic. There are probably larger deposits of anthracite in China than in any other country. The Shan-si coalfield covers an area of 55,000 sq.m.; one bituminous seam in this field is 20 ft. thick. In Hu-nan, anthracite coal, having a conchoidal fracture and comparable with the best known varieties is found. The strata in this district are greatly broken up, and the inclinations are often great. The total area of the coal measures in this district is estimated at 21,000 sq.m. An average sample of Manchurian coal gives the following analysis: Fixed carbon, 62; volatile matter, 20; ash, 10; moisture, 2; sulphur, traces.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, PRES. AND TREAS. ROBERT MCKEAN, SECY.
505 Pearl St., New York.
London Office: 6 Boulevard Street, London, E. C. 4, Eng.
CABLE ADDRESS "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for May, 1909, was 52,000 copies.

June 5, ...	11,000
June 12, ...	9,500
June 19, ...	9,500

None sent free regularly, on back numbers. Figures are live, net circulation.

The Copper Statistics for May

The report of the Copper Producers' Association for May was received generally in an optimistic way, but analysis of the figures does not seem to us to afford any substantial basis for joy. The accumulated stock was reduced by about 13,500,000 lb., but it does not by any means follow from this that the production of copper is now being used up faster than it is being turned out. On the contrary, the reduction of the accumulation in the hands of the refiners implies chiefly a transferal of the metal from one place to another. The exports in May were upward of 70,000,000 lb., a high figure. What was happening is reflected by the European statistics for May, which showed an increase of about 12,300,000 lb. in the visible supply.

Deducting the exports from the deliveries, there remains upward of 60,000,000 lb. that must have gone into second hands on this side, or was to some extent on lighters awaiting export. It is, of course, utterly incredible that domestic consumption has yet reached the figure of 60,000,000 lb. per month, which would be higher than the best on record. Undoubtedly some large manufacturers took a great deal of copper into their yards during May, providing for requirements for some time ahead. This is another way of transferring stocks.

The ominous feature about the statistics for May is the continued increase in the production, which averaged 3,818,000 lb. per day, against 3,785,810 lb. in April. The ratio of increase was larger in May than it was in April. It is well known that some large consumers of copper have taken in their requirements for many months ahead. The actual consumption of the world will have to make further strides in order to take care of the steadily increasing production and bring about a real diminution of stocks.

The real condition of affairs is reflected in the weakness of the market this week. Consumers have been well supplied and producers have much copper yet to sell. The visible supply at the middle of June, ascribed from abroad, shows a large increase, and the statistics at the end of the month will doubtless show a further augmentation.

The World's Production of Gold and Silver

According to our latest compilation of the official statistics so far as reported, with estimates for the minor countries from which official reports have not yet been received, the production of gold in the world in 1908 was 444,382,312, compared to \$411,294,458. The production in 1908 not only was the largest on record but also it showed a larger increase compared with the previous year than for any time since 1898. Large increases in the production were shown by the United States, Canada, Mexico, Russia, Rhodesia and the Transvaal. The production of British India was about the same as in 1907. The only important gold-producing country to show a decrease was Australasia.

In spite of the lower price for silver there was an important increase in the production of that metal, which amounted to 200,655,383 oz. in 1908, against 183,386,250 oz. in 1907. There was a large decrease in the production of the United States and a small decrease in that of Australasia, but there were very large increases in the production of Mexico and Canada and small increases in several of the South American countries. The decreases in the United States and Australasia are explained by the reduced outputs of some of the base-metal mines which yield silver as a by-product of copper and lead. The large increases in Mexico and Canada are explained by the extension of the application of the cyanide process to the treatment of silver ore in the former country, and to the larger production of the remarkable Cobalt district in the latter country.

Santa Rita and Chino

A lady saint and a Chinaman, whereby hangs a tale. Some time ago our friend, Thomas W. Lawson, favored us with a handsomely engraved communication to the effect that he would soon present to us, together with other selected persons, an important literary production. In due course of time, the latter appeared and turned out to be a book dealing with a new process and the Santa Rita mine, to which we have previously referred. In the natural order of events, the materialization of this publication should have been followed by a loud blowing of the

bazoo. Strange to say there was silence, and stranger still, the Santa Rita mine was brought out a few days later, under the name of the Chino Copper Company, by a well known house of bankers and brokers, without one mention of Mr. Lawson. Our readers are interested in having an explanation of this sudden shift.

Mr. Lawson intended to promote the Santa Rita company. He owned an interest in it and had options upon the other interests. He published his book before he had exercised his options. Just then certain unexpected events occurred that led Mr. Lawson to refrain from exercising his options and transfer them to the house that brought out the Chino Copper Company.

The Santa Rita mine has a large deposit of oxidized ore of very low grade, below which there is low-grade, disseminated sulphide ore, that has not yet been extensively developed. Mr. Lawson contemplated treating the oxidized ore by a new hydrometallurgical process. The new owners are directing their attention to the sulphide ore in the conventional way.

The Wage Question at Broken Hill

As has been heretofore noted in the JOURNAL, the miners at most of the large silver-lead mines in the Broken Hill district of New South Wales have been on strike for some time past, and there is no immediate prospect of a settlement. The strike and the subsequent proceedings present some peculiarities, which are of interest. Some of these are due to the Australian law of arbitration, which is generally considered to be favorable to the unions, whose political influence has been very strong.

To go back to the origin of the trouble, the Broken Hill Proprietary Company—the principal company in the field—which had been paying its men on a stipulated scale, settled by arbitration in 1903, agreed about the end of 1906 to make a general advance of about 12½ per cent. This advance was granted without any contest, in view of the high prices for lead and silver then prevailing, which made the increase possible. The example of the Proprietary Company was followed by the other companies in the field. The advanced rate was to hold for two years. At the close of that time, in August of

last year, the company decided to withdraw the advance, owing to the fall in the prices of metal. At the same time it offered the men, not simply a return to the wages of 1903, but a sliding scale, based on the price of lead, so that any advance in the metal would carry with it an increase in wages. This was not accepted by the men, who appealed to the Arbitration Court provided by Australian law, and who also decided to stop work, although the company offered to guarantee payment at the higher rate, if the Court should decide against it.

The action of the Broken Hill Proprietary Company was followed by the Broken Hill Block to Company, but after the men had struck the minor companies in the field generally gave way, and paid the higher schedule. When the case came before the Arbitration Court the two companies represented that a continuation of the 1906 schedule at present prices for lead and silver would force them to work without any profit, or at a loss, and that they would be compelled, under such circumstances, to close down altogether.

The Court, however, decided against the companies, not on the basis of their argument, but apparently entirely on the ground that the rate of 1906 represented the lowest point which could be regarded as a "living wage" in the district. It may be noted here that the rate for unskilled labor, under the award of 1903 was the same which had been paid for 10 years previously, and was 7s. 6d. (\$1.80) per day. The increase in 1906 brought it up to 8s. 7½d. (\$2.07) per day. This was the rate in controversy; miners in the district generally work on contract, and in 1908 averaged from \$2.76 to \$2.90 per day.

The Proprietary Company believed that the Arbitration Court had exceeded its powers in basing a decision, not upon the facts in the case, but upon its theory of the amount of a "living wage." Accordingly it appealed to the higher court. Some propositions for a compromise have been made, but not accepted. The latest reports state that the Appellate Court has approved the decision of the Arbitration Court, but solely on the ground that it had not exceeded its powers; the higher court not going at all into the merits of the case.

The Broken Hill laborers have accordingly gained a victory in one sense; but they do not seem likely to derive much benefit therefrom. The Proprietary Com-

pany has decided to continue work at its Port Pirie smelter to carry out certain contracts, but at the mines only to a limited extent. A large number of its former employees will be out of work altogether, as all of them have been for some months past.

Apparently the theory of the "living wage" is legally established in New South Wales; but in a way, probably not expected by the strikers, it will have a practical application to owners and employers as well as to employees. There is no legal way to compel owners to work their property at a loss. The price of such products as lead and silver depends on conditions beyond their control. If the men are unwilling to work except at a price which will make it impossible to produce the metals at some profit, the production must cease in time. A graduation of prices to wages would be possible only in the case of a producer who held an absolute monopoly.

The proper division of profits between owners and workmen is a complex question which, in all probability, will never be completely settled. The controversy at Broken Hill, apparently, has done little toward settling that settlement.

The Broken Hill Proprietary mine of New South Wales is admittedly nearing the end of its life. At the last semi-annual meeting of the company, the chairman of the directors stated that at the end of August, 1908, the ore reserves amounted to 3,000,000 tons. During the following six months 264,847 tons of ore were raised, leaving 2,735,153 tons. No considerable orebodies have been encountered during the last year, and the immediate prospects are confessedly disappointing. At the present rate of production the life of the mine will be about five years more. If no new orebodies are discovered in the meanwhile, this will be the end of a glorious career.

THE MINERAL INDUSTRY, Vol. XVII, is now on the press and should be ready for distribution before the middle of July. It will be a volume of about 1100 pages. The printing is being done directly from the type, no plates being made, wherefore there will be no reprinting. The edition being thus limited, subscribers are advised to send in their orders early. There will be no complimentary list and no copies will be sent to the press for review.

The California Eight-hour Law

The new eight-hour law for miners in underground mines and men in reduction works, is to be tested at once before the Supreme Court. Fred J. Martin, superintendent of the Utica Mining Company at Angeles in Calaveras county, was arrested for keeping a miner in the 603-ft. level of the mine for 8½ hours, which is a longer time than the new law permits. He was arrested and imprisoned, Judge McSorley, of the Superior Court, of Calaveras county holding that the law was constitutional. A petition for a writ of *habeas corpus* has now been filed in Mr. Martin's behalf, which brings the matter at once before the Supreme Court. The law is attacked on allegations that it is special legislation and that the title embraces more than one subject. The attorneys for Martin contend that the regulation of labor in "smelters and other institutions for the reduction or refining of ores or metals" can in no sense be germane to labor in "underground mines," so as to be included within the general scope of an act "to regulate the hours of labor in mines." It is contended that the title of the act is in conflict with the State constitution, which provides that every act shall embrace but one subject, which subject shall be expressed in its title. But if any subject shall be embraced in an act which shall not be expressed in its title, the act shall be void as to so much thereof as shall not be expressed in its title.

The expression of two incongruous and disconnected subjects in the title of the act can only have the effect of rendering the whole void for uncertainty. If the title had been left as it originally stood, only such parts as were not expressed in the title would have been void, but the title was amended, and this, the lawyers think, destroyed the entire act.

The title of the law as amended is "an act regulating the hours of employment in underground mines and in smelting and reduction works." It does not take in all kinds of mines, and is thus considered special legislation. Men can work, or be worked, in placers, hydraulic and river-bed mines and gold dredges for any length of time without restriction, but if they get the gold in underground mining they cannot work more than eight hours even if they wish; and if the superintendent permits them to do so he is subject to fine and imprisonment, as in the case of Mr. Martin, of the Utica. As predicted in one of these letters the matter has been brought to issue very promptly by the mineowners and operators of the State, who will jointly press the suit now commenced to test the constitutionality of the law. Frank J. Solinsky and Paul C. Mori of San Francisco, both well known mining lawyers represent the California Miner's Association and Mr. Martin.

The Psychology of a "Bull Market"

In America, a "bull market" in stocks is an event which supersedes all other considerations of the day, says *The Evening Post*. Up to a certain point in its history, popular comment on it is pretty much limited among people out of Wall Street, to remarks by business men and their clerks that "I see stocks are picking up," with the inference that "things ought to be better with us, after a while." The Stock Exchange is then regarded as an indicator which is watching general business and trying to get the correct gage of it. The rise goes on; one hears less about business conditions and more of the market itself as the primary consideration. Quiet readers of the afternoon paper at the club, men to whom Wall Street is a picturesque idea and nothing else, stroll up to the latest arrival from an office south of Pine street, to inquire, curiously, "What are you doing with things down there?" Inquiries from widows and orphans next begin to arrive, as to whether they had not better sell the bonds that were left to them in the will, and put the money into Tin preferred or Amalgamated Nickel. This is preliminary, if the ticker keeps at its duty, to those profound conferences on the ferryboats and around the lunch counters, over the "inside pointer," which John or Henry got from a first-rate source, and which means ten points on the narrowest figuring. If the episode goes still further, it sometimes supersedes not only horse racing, but the standing of baseball teams, as the nearest topic of common interest.

It is the business of our high financiers to encourage and promote this pleasant pastime, and the way of doing it has been fairly well marked out by experience. If there are "new deals" under way in the finances of companies whose shares are listed on the Stock Exchange, they must be announced at judicious intervals, according as stimulus is needed for the "bull movement" and each of them must be held back until the psychological moment— which, naturally, means until the stock has been accumulated by the people with "inside information," has been bid up to very much higher prices, and is ripe for transfer in exchange for the outside public's cash. This is what Wall Street calls "distribution"—a term which, since it remotely suggests benevolence, is more favored than the term, "unloading," whose associations are more harsh. The rest of the history of the episode depends on circumstances; it is these which provide the gambling element which, after all has been said, is as dear to high as to low finance.

According to THE MINERAL INDUSTRY, 1908 was the first year in which magnesium was produced in the United States. The output amounted to 500 lb. worth \$500.

Mineral Production of Virginia

By THOMAS LEONARD WATSON*

The statistics of production and value of minerals in Virginia for 1908—not including metals—collected by the Virginia Geological Survey in cooperation with the Division of Mineral Resources of the U. S. Geological Survey, clearly indicates the effect of the recent business depression arising from the monetary troubles. The decrease is especially noticeable in the larger industries, such as coal and coke, clay products, iron ores, stone, talc and soapstone, etc., but some of the smaller ones, of which there are many, show a marked increase. The total value for the year 1908 is \$12,059,310, or about 70 per cent. of the production for 1907.

The quantities and values of the principal mineral products were:

	Quantities.	Values.
Coal.....	Sh. tons 4,224,821	\$3,881,448
Coke.....	" 1,158,517	2,093,374
Iron ore.....	Lg. tons 645,460	1,372,802
Pyrite and pyrrhotite.....	" 117,440	389,808
Manganese ore.....	" 6,144	62,779
Miscellaneous minerals.....	Sh. tons 27,04	114,572
Mica, sheet.....	Lb. 13,427	7,346
Mica, scrap.....	Sh. tons 461	
Talc and soapstone.....	" 18,623	335,068
Mineral waters.....	Gal. 2,316,619	434,742
Total.....		\$8,692,039
Add clay and stone.....		3,367,271
Total values.....		\$12,059,310

Miscellaneous minerals include barytes, gypsum, feldspar and mineral paint. The quantities and values of the building materials produced were as follows:

	Quantities.	Values.
Granite.....	Lg. tons 412	\$321,530
Limestone.....	" 41,078	272,306
Slate.....	" 41,078	194,346
Millstones and sandstone.....	" 8,554	8,554
Sand and gravel.....	" 226,782	226,782
Clay.....	Sh. tons 585	3,619
Brick and tile.....	M. 196,034	1,523,191
Sand-lime brick.....	" 7,074	40,534
Lime and cement.....	Bbl. 1,472,564	774,399
Total values.....		\$3,367,271

There was no production of arsenic, asbestos, fluorspar, graphite, quartz, rutile, nickel, or phosphate in Virginia, in 1908. Considerable development work was in progress during the year in the Nelson county rutile area. The results were encouraging and it is expected that the area will again be a producer in 1909.

Statistics of THE MINERAL INDUSTRY show that in 1908 the United States produced 32,000 short tons of calcium chloride valued at \$224,000. In 1907 45,000 short tons valued at \$450,000 were produced.

The 1908 production of zinc ore in the United States was 838,377 short tons against 902,923 short tons in 1907. These are the figures obtained for THE MINERAL INDUSTRY.

*State geologist, University of Virginia.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Electric Mine Signaling

The arrangement of electric signals at the Grand Hornu mine, described in the JOURNAL of April 24, 1909, is similar in many respects to that which has been in use in a number of collieries in the United Kingdom, for nearly thirty years. As far as there is any difference between the arrangements at the Grand Hornu mine and those in use at British collieries, the arrangements at Grand Hornu appear to me to be not so good. The use of the current from an electric-power service, in place of batteries, is a natural de-

might go over the place again and again, and not see it.

We found in those days and the matter has not altered since, that a wire in which the current was always present, if fixed in the shaft, was much more liable to be eaten in two than the wires in which currents were only passing when the signal was being given. I found the best method was to have a battery at the top to work the down signal and that between bank and engine house, and another battery at the bottom to work the up signal.

The modern equivalent of this would be a connection from a small motor generator at the top, to work the down signals,

the different signal wires, and the tendency is to use armored cables in the shaft for everything now. I do not see, either, the advantage of using alternating currents as far as the working of the bells is concerned. A bell to work with alternating currents is a more complicated affair than one to work with continuous current. A familiar instance of a bell working with alternating currents is the call bell of the telephone apparatus.

It also appears to me not to be quite sound for the home bell to ring at the same time as the distant bell. According to the description of the signals at the Grand Hornu mine, the onsetter at the pit bottom would ring his own bell, at the same time as he rang the bells on the bank and in the engine house. One of the most important conditions that were given to me, when I was working out the shaft signal thirty years ago, was that

SHAFT SIGNALS WORKED BY CURRENT FROM MOTOR GENERATORS AT TOP AND BOTTOM

SHAFT SIGNALS WORKED BY BATTERIES

velopment but to my mind the use of alternating currents for signals is hardly wise, and the use of a live wire in the shaft is also unwise.

In the early days of electric signaling, we had a great deal of difficulty with shaft signals, principally owing to the wires in the shaft getting eaten away. If the insulating envelope of the wire was damaged even slightly, the water that is always present in mine shafts found its way through to the copper and quickly ate it in two, with the result that it not only stopped the signals but it was difficult to find. With long experience, one got pretty expert at finding these faults but anyone coming fresh to the work,

and the signals between pit top and engine house, and the current from another motor generator at the bottom to work the up signals. It is a simple matter to arrange a motor generator, taking current from a three-phase supply service, and generating continuous currents for the signals, and possibly for other work, both at the top and bottom of the pit and in any intermediate seams.

One disadvantage of the use of alternating currents for signaling is that it is absolutely necessary to have the signaling wires in one cable, twisted round each other, or to place them very close together. It would not do to have separately armored or lead covered cables for

nothing of the kind must take place. The reason I think is obvious, viz., that confusion may be caused by it.

The special rules for colliery working in the United Kingdom state very clearly that a certain number of raps on a bell, or the equivalent, must be given and a certain number of raps received in reply. It might happen that the onsetter was signaling at the same time as the bankman, though that would not often occur, and the results might be disastrous. I may mention that while engine plane signals have been almost universally adopted in every colliery in the United Kingdom, shaft signals have only been taken up at comparatively few. The ac-

companying diagrams show the connections of the signals as they are fixed in British collieries, with batteries, and as they would be arranged for taking current from motor generators.

SYDNEY F. WALKER.

Bath, England, May 12, 1900.

Filing System For Technical Papers

A mining engineer in the practice of his profession is called upon to move from place to place a great deal and he soon finds that he cannot afford to pack a large library around with him. A standard work on milling, one on smelting and another on ore deposits will probably form the extent of his library especially during the earlier years of struggling to the top. During these years a man must depend almost wholly on the magazines and journals of his profession to keep him posted. Text-books are necessarily a year or more behind the progress. The articles in the technical press are written by the men in the field, and are alive and up-to-date. Therefore a man who supplements his few standard works on mining and metallurgy with a filing system by means of which important articles from current literature can be filed for future reference is sure to be up-to-date in his reference library.

I have such a file which contains all the important articles bearing on methods of mining, milling and smelting, costs at different plants, financial and other company reports, geological data, discussions, etc., which have appeared in several American and Canadian journals during the past four or five years. This collection contains about 7000 pages, yet the whole file can be carried in one end of a suit case. There is probably nothing new in the method of making up this file and its index, yet it requires so little work in comparison to its great value that a short description may be of interest to readers of the JOURNAL.

The indexing is done in a small loose leaf pocket-book. This book is leather covered and has three steel rings which can be opened or closed by means of a sliding lever in the cover of the book. Such books are carried by all stationers. The one I use is 5x7 in. in size and has indexing letters from A to Z. Under each letter several pages can be inserted and each one alphabetically marked at the top as Aa, Ab, etc.

Should an article be devoted to one subject, as for instance a description of the Shannon concentrator, it would be entered in the index under

Sh—Mills, description of
Shannon Cu. Co. 325.

Also, under *Ar*—Arizona—Shannon Cu. Co. 325. I would also cross-index this to *Co*—Copper in Arizona, Shannon Cu. Co.

If the article also described the smelting plant and mining methods, under "*Sm*—Smelting" would be entered the page describing that operation and under "*Mi*—Mining at Shannon Cu. Co." the page on which is the description of that operation. Then under *Sh*—would be a heading, Shannon Cu. Co., and page numbers of all articles relating to that company or plant would be entered. In this way each article is divided into several heads and each one is indexed under its proper letter. Should I want general information on the Shannon Copper Company, I would refer to index letter *S*, turn to page *Sh* and the page numbers of all articles of every kind referring to that company would be together on one line thus:

Shannon Cu. Co. 318-577-618-1141.

However, should I wish to know only cost of production at that plant I would refer to index letter *C*, and find such items under

Co—Cost of
Shannon, milling at, 318
milling at, 618
producing Cu. qt, 1141.

The pages are torn out of the journals and numbered in the center of the bottom margin. These are then placed in manilla envelopes large enough to hold two hundred pages without folding. The envelope is marked to show what pages are included within. In order to keep the pages together two holes are punched in the top margin and copper fasteners put through and clinched, thereby binding together the two hundred pages. An extra envelope can be used for unindexed sheets yet even the busiest man if he finds time to read the articles can do the indexing as he goes over the articles and with but little loss of time.

Any number of pages can be placed in the index book up to its capacity. I have over 7000 pages of articles indexed yet the small book is not one-quarter full and can easily be carried in the pocket. While the file of articles can be carried in the suit case and still leave room for other necessary articles; yet what a live comprehensive reference library it is.

D. F. HALEY.

West Gore, Nova Scotia, May 20, 1909.

Prevention of Mine Accidents

The Committee on Prevention of Accidents in Metalliferous Mines, appointed by the American Mining Congress, expects to make a report at the forthcoming meeting of the American Mining Congress at Goldfield, Nev. This report will take the form of the presentation of a code covering provisions that are deemed necessary to promote safety in mining. Much importance is attached to this report, inasmuch as it is likely to be the basis for legislation by several States

Already a commission to draft a mining law for Arizona has been appointed, and that commission is awaiting the report of this committee.

In the first report of this committee, published in the ENGINEERING AND MINING JOURNAL of Dec. 5, 1908, and republished in pamphlet form by the American Mining Congress, summaries of the existing mining laws of several States were presented. The hope was expressed that these publications would have led to suggestions as to provisions that ought to be included in, or excluded from, a composite and improved mining law.

The committee now urges particularly that anyone having suggestions to offer respecting the workings of the existing laws of Colorado, Montana, Idaho, Missouri, and other States, or features in those laws that should be excised, or new provisions that should be incorporated, communicate promptly with the unsigned, in order that the committee in its deliberations may have the benefit of such suggestions.

W. R. INGALLS,

Chairman.

505 Pearl street, New York, June 11, 1909.

Michigan Gypsum

By JAMES L. NANKERVIS*

Gypsum is found in remarkable abundance and purity at Grand Rapids and Alabaster, and in moderate quantities at various other places. This mineral is very properly classed among the useful products of the State and its production and manufacture form an important and a growing industry. The output of gypsum in Michigan in 1908 was 250,000 tons, valued at over \$700,000. While the growth of the industry has been somewhat slow, yet it has been steady, wholesome and continuous. The stratum of gypsum at Grand Rapids is 18 to 20 ft. in thickness, and is found from 1 ft. to 16 or 18 ft. below the surface; it is fully 1000 ft. in extent, affording a very large supply to draw upon.

The development of the gypsum industry in Michigan is practically confined to Grand Rapids where the mineral is produced in considerable quantities and is ground and prepared as a basis for wall tintings, wall decoration, stucco work, plasters, fertilizers and other uses. For wall tintings and decorations alabaster and allied gypsum products are among the best things made. On account of the excellent sanitary properties of the articles and the ease with which the different preparations may be applied, they are becoming popular in the United States and in many parts of Europe.

*Ex-commissioner of mineral statistics, Calumet, Mich.

Production of Various Minerals in Kentucky During 1908

By CHARLES J. NORWOOD*

Statistics are now available of the production of commercial coal, fluorspar and barytes in Kentucky for the calendar year of 1908. I have no hesitation in saying that these statistics are as complete as it is possible to collect. Data relating to the production of commercial coal are gathered monthly by the mine-inspection office and are checked and rechecked throughout the year, while the data for fluorspar and barytes are gathered by the Kentucky Geological Survey through personal visits made by F. Julius Fohs, of the Survey, and are checked in various efficient ways.

OUTPUT OF COAL

The production of commercial coal amounted to 9,805,777 short tons, a decrease of 630,284 tons, as compared with 1907. The losses occurred in the western and southeastern districts, the loss in the former being 526,186 tons, and in the latter 184,687 tons. The northeastern district gained 80,589 tons. The output for 1908 by counties, arranged according to districts, is given in the accompanying table.

KENTUCKY COAL PRODUCTION IN 1908.

WESTERN DISTRICT.

County.	Tons.
Buller	4,068
Christian	33,191
Daviess	52,658
Henderson	226,152
Hopkins	1,772,253
McLean	97,287
Muhlenberg	1,774,314
Ohio	602,316
Union	513,015
Webster	558,442
Total.	5,634,596

SOUTHEASTERN DISTRICT.

County.	Tons.
Bell	1,434,742
Knox	520,089
Laurel	212,585
Pulaski	69,634
Whitley	813,541
Total.	3,050,591

NORTHEASTERN DISTRICT.

County.	Tons.
Boyd	79,763
Breathitt	24,043
Carter	78,509
Floyd	32,857
Johnson	154,159
Lawrence	21,751
Lee	92,533
Morgan	62,290
Pike	561,585
Total	1,120,500

The disposition of the product was as follows: Sold locally, 301,283 tons; used at the mines, 201,273; converted into coke, 85,449; shipped to market, 9,157,772. Of the total output, 70,413 tons were of cannel coal. The average selling value of the latter, at the mines, was \$2.430 per ton. With cannel included, the average selling value of all coal was \$0.907 per ton, but dealing with the bituminous alone, the average selling price per ton

for the various districts was as follows: Western, \$0.9081; southeastern, \$1.1414; northeastern, \$0.9580; general average, \$0.9856; total value, \$9,605,025. When comparing figures issued by the U. S. Geological Survey with those given by this office, it should be remembered that the former organization undertakes to report the production of all "banks," whether large or small, while this office reports only commercial coal.

Of the coal shipped from the mines, 57.74 per cent. was sent to other States, the western district and northeastern district being the largest shippers to outside markets. A fraction more than 56 per cent. of the total product was mined by machine, the proportion in each district being as follows: Western, 70.52 per cent.; southeastern, 32.56 per cent.; northeastern, 40.52 per cent. In the production of coal, 18,611 persons were employed of which 14,522 were engaged under ground and 4089 employed at surface works, including coke ovens. But little coke was made during the year. The St. Bernard ovens, in Hopkins county, turned out 36,416 tons; the ovens of the Ohio Valley Coal and Mining Com-

PRODUCTION OF FLUORSPAR IN 1908

The statistics of the production of fluorspar were gathered with especial pains to obtain correct returns. As in 1907, the production was confined to Crittenden and Livingston counties. The tonnage mined was 25 per cent. less than in 1907, though greater than in 1906, and the shipments fell below those of any year since 1899. The tonnage held in stock at the beginning of 1909 was greater by almost 3000 tons than for any previous year. The amount of lump shipped was small, being almost entirely replaced by gravel. The production came from nine mines, the bulk, in fact, from five, whereas more than twice that number were necessary to yield about the same amount in 1906 and 1907, showing that with a certain amount of development any of the good fluorspar mines can become much larger producers. The statistics of production, shipments,* etc., for 1907 and 1908 are arranged for comparison in the accompanying table.

In 1908 the prices in Kentucky ranged from \$4.35 to \$6 for gravel, \$5.50 to \$7 for second- and third-grade lump, and \$9 to \$15 per short ton for ground fluorspar.

FLUORSPAR PRODUCTION 1907 AND 1908.

MINED.		MARKETED.								IN STOCK Dec. 31.
Year.	Tons.	Gravel.		Lump.		Ground.		Totals.		
		Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.	
1907	15,918	6,133		1,033		6,030		13,496		8,876
1908	12,010	2,840	\$14,226	307	\$1,828	3,176	\$32,588	6,323	\$48,642	12,899

pany, in Union county, produced 1837 tons; the ovens of the Straight Creek Coal and Coke Company, in Bell county, were idle nearly all the year, producing only 100 tons.

There were 39 fatal accidents, as follows: Inside mine, 35; in shaft, 1; on surface, 3. This was an increase of 7 over the number for 1907. Considering accidents inside the mine only, the increase was 10. This was due to two explosions caused by blown-out shots and to an increase of 5 in the number of deaths due to falls of top. It is not improbable that the increase of fatal falls of top was in some measure due to the crippled condition of the mine-inspection bureau for a good part of the year; the increases occurred in districts that were without inspectors for some time, whereas in the districts having inspectors there was a decrease. In one of the explosions a blown-out shot caused the explosion of a keg of powder, killing 3 men; in the other, a blown-out shot set fire to coal dust and 9 men died from the effects of the afterdamp. In this State, blown-out shots seldom occur except where coal is shot on the solid. Mining on the solid should be explicitly prohibited by law; there seem to be difficulties in the way of many of the operators who may attempt to make a "rule" against it.

The average price for all grades was \$7.69. The first six months of 1908 proved the dulllest for the fluorspar industry that had been experienced for a number of years. The companies report a falling off in business of from 35 to 80 per cent., averaging less than half as compared with the same period in 1907. This, however, was in accord with the general depression in the business of the country, the chief factor affecting the fluorspar industry being the slack demand that followed the shutting down of iron and steel plants. Since the larger number of shutdowns were in the South, the reduced demand for fluorspar from that section was especially felt by Kentucky operators. The demand for fluorspar in other industries, especially glass, was also less. The resumption of work at many of the iron and steel plants, and the blowing-in of new furnaces during June, especially in the South, caused a better demand for the remainder of the year.

But when the demand from steel plants increased, there were still two factors which prevented Kentucky from getting its share of the business, namely, underselling by one of the large Illinois producers, and the severe competition offered by the imported English fluorspar. The greater factor is the annual importation of 100,000 tons of gravel fluorspar, duty free,

*State geologist and chief inspector of mines, Lexington, Ky.

from English waste dumps. The cost of this product, according to excellent authority, is \$2.19 to \$2.59 per long ton laid down at Partington and Liverpool. The ocean freight rate is \$1.22, making a total of \$3.41 to \$3.87 per long ton at Atlantic ports. The freight rate from Baltimore to Pittsburg is \$1.50, making a total cost of \$4.91 to \$5.37 per long ton, or \$4.38 to \$4.74 per short ton, at Pittsburg. The sale price at Pittsburg is said to be such as yields the English shippers a fine profit.

On the other hand, the cost of producing gravel fluorspar in western Kentucky (not allowing for mine depreciation, etc.) is reported by one company at \$4.48 per short ton. The average selling price in 1908 was \$5.01. Another company gives as the average cost of all grades \$6.22 per ton, the average selling price for 1908 being \$7.60. The freight rate from western Kentucky to Pittsburg is \$2.50 per ton. Manifestly, it is impossible to compete with the duty-free foreign fluorspar, and unless a countervailing duty is laid on gravel fluorspar one of the promising young industries of this State must suffer greatly. Since the average maximum amount of fluorspar used per ton of open-hearth steel does not exceed 15 lb., an equalizing tariff laid on gravel spar would not materially affect the cost of steel production.

Kentucky producers, and some of the Illinois producers as well, have refused to sell fluorspar unless a living price can be obtained and have, therefore, either curtailed production or piled up large stocks. In the discussion of the fluorspar and tariff question it has been asserted by some that in this country, as in England, the spar is a by-product from lead mining. That this is entirely erroneous, however, is shown by the fact that in the Kentucky-Illinois district, whence comes practically all the American spar, the lead production is small; there were only 107 tons of lead concentrates produced from more than 12,000 tons of Kentucky fluorspar in 1908.

silver probably came from some lead concentrates made at a Kentucky mill from Rosiclare, Ill., ore.

The following companies mined or marketed fluorspar from Kentucky mines during 1908: Albany Mining and Investment Company, Marion; Blue Grass Fluorspar Company, Princeton; Great Northern Mining and Development Company, Marion; Indiana & Kentucky Fluorspar and Lead Mining Company, Marion; Kentucky Fluorspar Company, Marion; Sunnybrook Lead and Fluorspar Company, Marion; and R. L. Moore & Co., Marion. The following did development work: James M. Pearsons, Marion; Pope Mining Company, Salem; and the Kentucky & Indiana Mining Company, Francis.

BARYTES IN 1908

Notwithstanding that in "Mineral Resources" for 1906 and 1907 Kentucky was assigned to a very minor position as a producer of barytes, and that in articles on barytes by various "experts" this State is not even named, Kentucky is really a very respectable producer of that mineral, and it is the belief of the State Geological Survey, as the result of field work that has been in progress for some months, that the Central Kentucky district is, all things being considered, the greatest barytes district in this country.

The production for 1906 amounted to 3375 short tons, valued at \$15,187; for 1907 it was 9435 tons, valued at \$44,059. In 1908 the amount mined was 11,051 tons. Of this a certain amount was used for making blanc fixe, concerning which we may not publish details, since the one concern making it does not authorize such publication. During the year 5233 tons of crude, valued at \$21,504, and 3300 tons of ground, valued at \$39,600, were shipped and a certain amount was stocked. At the close of 1908, 5904 tons were reported in stock. The average value of crude barytes was \$4.11 per ton, and that of ground, \$12. The average prices for both crude

samine, Lincoln, Owen, Scott and Woodford. Boyle, Fayette and Garrard were the largest producers, in the order named. Excellent deposits also occur in Henry, Mercer and Russell counties, especially in the first two, but there was no production in 1908.

The Dix River Barytes Company intends to erect a mill for grinding and bleaching barytes at Danville, Boyle county, and the Kentucky Barytes Company contemplates the erection of a plant for the production of blanc fixe and barium by-products; the company now has a grinding plant at Nicholasville, Jessamine county. The Mutual Mining Company is enlarging its blanc-fixe and lead-fume plant, and is adding equipment for the manufacture of paint. No lead or zinc shipments were made from the Central Kentucky district in 1908. About 60 tons of lead concentrates were produced. The Mutual Mining Company manufactured blanc fixe, sodium sulphide, and depilatory throughout the year.

The field study of our barytes deposits is in the hands of F. Julius Fohs, by whom the statistical data were gathered. As the work of the Survey proceeds a large number of veins have been brought to light, some of them extending four to five miles in length. In Fayette county alone 32 veins have been investigated, two-thirds of which Mr. Fohs considers profitably workable. The average width of the veins is 3 ft., but enlargements occur measuring over 10 ft. in width. The barytes is known to extend downward, nearly vertically, to a depth of 250 to 300 feet.

Annual Report on Production of Butte Mining Companies

The annual reports of the mining companies, required by law to be filed with the county assessor, were made public last week and show the earnings for 1908.

REPORT OF BUTTE MINES FOR 1908.

	Anaconda.	Boston & Montana.	Butte & Boston.	North Butte.	Washoe.	Butte Coalt.	Trenton.	Parrot.
Tons of ore extracted	1,316,893	1,185,142	355,702	191,951	208,675	424,752	168,818	147,858
Gross proceeds	\$11,963,134	\$12,087,073	\$3,212,726	\$4,048,329	\$1,543,062	\$3,712,322	\$1,212,725	\$1,057,385
Cost of mining	5,460,937	4,730,533	1,322,887	1,630,167	759,938	1,623,980	614,015	608,138
Freight on ore	162,444	763,288	75,079	59,118	25,524	70,691	20,275	21,733
Cost of reduction	2,946,242	4,285,768	835,923	1,413,600	604,154	1,568,488	350,376	439,784
Cost of marketing	1,313,642	902,698	329,637	3,108,886	1,389,618	3,263,161	1,103,826	1,069,606
Total cost	9,883,263	10,682,286	2,568,528	5,139,442	153,441	459,160	136,898	def. 12,221
Net earnings (1908)	2,079,871	1,404,783	616,198	1,113,647	246,096	71,810	67,259	def. 139,372
Net earnings (1907)	1,132,875	1,561,061	295,605					

None of the 107 tons of lead concentrates was sold owing to the low price of lead in 1908. No zinc was mined, but 56 tons of zinc carbonate were shipped from the Crittenden Springs and Keyes mines. Perhaps it will be well to state here that the returns of 2 oz. of silver per ton from some "Kentucky" lead reported by Mr Siebenthal in "Mineral Resources" for 1907 was an error; no Kentucky lead has yet shown commercial silver returns. The

and ground mineral were less than for 1907, and the indications are that the prices for 1909 will be still less.

Although there are deposits of barytes in Caldwell, Crittenden, and Livingston counties, in western Kentucky, the barytes industry is still confined to the Central Kentucky district, and in 1908 work was carried on in thirteen counties, namely: Anderson, Bourbon, Boyle, Clark, Fayette, Franklin, Garrard, Harrison, Jes-

se, Lincoln, Owen, Scott and Woodford. In view of the low price of copper and the general business depression prevailing during the year, the companies, as a group, have made a good showing. The total net earnings for the year were \$6,732,015 as compared with \$4,648,254 for the year 1907. The accompanying table embodies the reports of eight of the large companies, also the net earnings of the various companies for 1907 by way of comparison.

Personal

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

Henry F. Lefevre has returned to New York from Nicaragua.

Julius W. Hegeler, of Hegeler Brothers, Danville, Ill., has been visiting New York.

T. H. Leggett has returned from a sojourn of several months in Sonora, Mexico.

W. C. Thomas, of Salt Lake City, Utah, has gone to Wales for a vacation of four months.

J. Parke Channing has returned to New York and will be here until the end of this week.

Elton W. Walker has returned to Detroit, Mich., from a trip to the silver districts of northern Ontario.

Ernst Schmatolla, of London, has established an office as consulting engineer at 150 Nassau street, New York.

H. C. Wilmot has opened an office as consulting mining engineer in the Newhouse building, Salt Lake City, Utah.

Jay P. Graves, of Spokane, Wash., managing director of the Granby Consolidated Company, is recovering from a serious illness.

Dr. Wilbur A. Hendryx, manager of Hendryx Cyanide Machinery Company, of Denver, Colo., is in New York on professional business.

George Alexander, manager of the Ferguson Mines, Ltd., and the Kootenay Ore Company, has returned to Kaslo, B. C., having spent the winter in Europe.

Charles H. Gitsch, recently of Park City, Utah, has been appointed superintendent of the Antelope Spring and Nevada Superior mines in Humboldt county, Nevada.

C. S. Herzig, who has been in Nicaragua for a number of months examining mines on behalf of the Oroya Brownhill Company, Ltd., of London, is expected in New York soon.

Lester W. Strauss is on his way to the western part of the department of Ayacucho, Peru, to examine a partially developed gold prospect. He expects to return to Lima, Peru, in June.

James McEvoy, formerly with the Geological Survey of Canada, has gone into the big coal district lying between Banff and Edmonton, Alberta, for the German Development Company, of Ottawa.

John Fritz, the veteran ironmaster—well called "the father of the American iron trade"—has presented \$50,000 to Lehigh University at Bethlehem, Penn., to be used to build and equip a metallurgical laboratory.

J. C. Gwillim, professor of mining at the School of Mines, Kingston, Ont., is spending a week or two at the St. Eugene mine

East Kootenay, B. C. Last month he did some geological work near Hosmer, Crow's Nest Pass.

James Hargreaves has resigned as mine manager for the Canada West Coal Company, Ltd., Taber, Alberta, to become superintendent of the Alberta Consolidated Coal Company, operating about four miles west of Taber.

George W. Schleuderberg, who has had charge of the mining department of the Pittsburgh Coal Company since its organization, will retire from that position July 1. He is one of the oldest operators in the Pittsburgh district.

K. C. Parrish sailed recently from New York to resume his duties as manager of the Andes Mining and Development Company in the district of Guamoco, Colombia. Part of his time will be spent in making mine examinations for other interests.

Louis A. Wright has been appointed consulting engineer in the Southwest and Mexico to the General Development Company; also consulting engineer to the Miami Copper Company. His headquarters will be at Globe, Arizona, for at least a year.

John D. Ryan succeeds the late H. H. Rogers as president of the Amalgamated Copper Company. B. B. Thayer takes Mr. Ryan's place as president of the Anaconda Copper Company. F. P. Addicks, vice-president of the Amalgamated is now vice-president of the Anaconda also.

Dr. Alfred C. Lane has resigned his position as State geologist of Michigan, to take effect Sept. 1 next. He expects then to take a position at Tufts College, and also to be able to concentrate his attention on the study of certain geological problems having a direct bearing upon mining.

H. A. Prosser resigned, on June 1, his position as metallurgical director of the United States Smelting, Refining and Mining Company, a concern with which he had been connected practically from its beginning, during which time he supervised the construction of the smeltery and refinery at Chrome, the refinery at Grasselli, the smeltery at Kennett, Cal., and the enlargement of the smeltery near Salt Lake City. Mr. Prosser has associated himself with Arthur L. Walker, and the firm, under the name of Prosser & Walker, has opened an office at 42 Broadway, New York, as consulting metallurgical engineers.

Obituary

Frank A. Lucy was killed June 7 by falling down the main shaft at the Florence mine in Goldfield, Nev. He had been prominent in the district and in other parts of Nevada for several years, and had recently been appointed superintendent of the Florence.

Louis G. Laureau died at Yonkers, N. Y., June 6, aged 68 years. He was long

associated with the late Alexander L. Holley, as his chief assistant, was for a while a member of the firm of Gordon, Strobel & Laureau, and for many years acted as a metallurgical expert in patent causes. He possessed an accurate knowledge of the steel industry of this country, and of Belgium and France.

Societies and Technical Schools

Georgia School of Technology—The latest catalog of this school at Atlanta shows courses in chemistry and chemical engineering; also in geology and metallurgy, especially the metallurgy of iron. The course in chemistry especially appears to be thorough and comprehensive.

University of Utah—The junior class in mining engineering is making a geological examination of the Pioche district under the direction of the Department of Geology. The class expects to spend six weeks in the district in surface and underground mine surveying and examination. The senior class recently returned from a month's trip throughout the West, visiting important mining districts.

Wisconsin State Mining Trade School—Three students graduate from this school, at Platteville, Wis., this year. This is the first class to graduate from the institution. These men will enter the employ of mining companies in the Wisconsin zinc district. All the other members of the student body will be engaged for the summer by some of the mines of the district.

Missouri School of Mines—A mining experiment station is to be established at Rolla. The legislature appropriated \$10,000 at the last session for this purpose, and the executive committee of the board of curators, has decided to begin work on the new station immediately and have it ready for work by Sept. 1. The experiment station will be in charge of the assistant professor of mining. An assistant for the experiment station will also be appointed.

The graduating exercises at Rolla were held June 9, when 37 men received degrees.

Chemical, Metallurgical and Mining Society of South Africa—At the general meeting in Johannesburg, Transvaal, May 15, the following new papers were read: "Stope Measurements," by O. S. Tonnesen (illustrated). "The Influence of Moist Air on Quicklime," by James Gray. "The Telluride Gold Ores of Cripple Creek, Colo.," by Thos. B. Crowe. The following papers came up for final discussion: "Precipitation of Cyanide Solutions by Zinc; a Comparison of Results and Costs," by Allan J. Clark. "Unskilled White Labor in Mining," by Tom Johnson. A number of other papers were ready for discussion.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Denver, Salt Lake City, Goldfield, Colbalt, Mexico

REVIEWS OF IMPORTANT EVENTS

San Francisco

June 11.—The State president of the Western Federation of Miners is at present very actively engaged in organizing miners' unions, more particularly in Sierra county and northern Nevada county. The attempt to do this in Amador county was not at all successful. The president expects to unionize all camps where a membership of 20 can be obtained, that number being requisite to obtain a charter.

The largest gold dredge yet constructed in the Yuba field has just been completed at Marigold, at a cost of about \$200,000. The machinery, now being installed in the hull was built at Marysville in the shops belonging to the dredging company. This dredge is expected to dig 45 ft. below pond level and to stack 45 feet.

Chas. S. Warren, of Butte, Mont., R. E. Bannan, W. W. Warren, of Gold Circle, and Frank G. Mitchell, of Cleveland, O., have bonded several mining properties in Yuba county for \$70,000 and work will soon begin on a large scale. Included in the bond are the Red Cross mine near Indiana ranch, owned by Krupp & Quinlan; the Good Templar, 30 miles east of Marysville, owned by Williams Brothers; and the Merriam property. There are small mills on both the Red Cross and Good Templar.

The dispute between the city of Oroville and the Indiana Gold Dredging Company, which has lasted a long time, has finally been settled. The injunction against the dredging company for interfering with the free flow of the water in the Feather river, has been removed. The dredge company agrees to level all the cobble piles it makes with its stacker as it goes along, not leaving them to form a barrier in the river bed. The company will also reimburse the city for the money spent in prosecuting the case, and will in return be permitted to continue operations until its land is dredged out. This is one of the two dredging companies in the State working ground where the cobble piles had to be left in the direct river bed. Most of the dredges are operating some distance from the rivers proper.

At the same place the Pennsylvania Dredging Company has settled its difficulties and agreed to reduce its cobble piles by leveling them off. No other dredges there are working in the river bed.

The local mint has just made a record run on gold coinage. This week it finished a 50-day run on gold, amounting all together to \$52,062,500 or \$1,070,000 daily for the 50 days. On the last day

the coinage was \$1,520,000 gold. A large amount of gold had collected and large quantities have been coming in lately, but it has now been pretty well cleaned up. The Alaska and Klondike gold will now be coming in for the season as well as much California and Nevada gold, so there will still be plenty to do.

Lieutenant Chas. L. Leeds of the Corps of Engineers, U. S. A., has been appointed a member of the California Débris Commission which, under the Caminetti law, has charge of the conduct of hydraulic mining in certain portions of the State of California. Since the retirement of Col. W. H. Heuer, the miners have had rather a hard time of it as the new members hold rigidly to the strict letter of the law and have not, thus far, evinced any special friendship toward the miners, or encouraged the hydraulic mining industry in any manner. There has been much complaint on the part of miners, but the operation of the law has been in the hands of the Commission entirely, they having the final decision on all questions relating to hydraulic mining. There is a hope now that the new member will take an interest in the hydraulic mining question, look after details, and have some little sympathy with the cause of the miners.

The new find in the Old Cape mine four miles east of Humboldt, Siskiyou county, is in one of the old tunnels. In addition to the gold and silver there is a good percentage of copper so that the ore will have to be shipped to a smelter. The property is now owned by Bulis & May. In former days there were no smelters near by and the "base" ore could not be worked, the owners being satisfied to take out what gold they could and let the balance go.

The old camp of Challenge Mills, Yuba county, is again showing activity after many years of idleness. A great deal of prospecting is being done by men from Nevada. The old placers are now yielding from \$500 to \$1000 per day during the water season.

The Supreme Court has reversed the decision of the lower court of San Diego county giving judgment for \$116 against H. H. Markham and Geo. Coffin, president and secretary of the American Boy Mining Company, charged by a stockholder with having misappropriated that sum from the company. The American Boy company some time since bought the adjoining American Girl claim and formed a new corporation. It was stated in the

complaint that Markham and Coffin had given shares in the company to friends without compensation. It was shown to the court, however, that the money had been utilized in promoting the development of the mines.

Butte

June 10.—President Anderson, of the Idaho Smelting and Refining Company, states that he hopes to effect an agreement among the company's creditors whereby operations may be resumed at the smelter. The control of the company's affairs is now in the hands of Temporary Receiver Bruce Blake, appointed by the Federal bankruptcy court. Mr. Anderson believes that the creditors will agree to an arrangement for the settlement of all claims and thus avoid the heavy costs attendant upon the completion of bankruptcy proceedings.

In March of this year, E. W. Beattie, of Boston, secured a judgment against the Bald Butte Mining Company for the sum of \$20,145. A petition asking for leave to intervene in the suit has been recently filed by Frank J. Edwards, of Helena, a stockholder of the company, who asks that the case be reopened and that he be allowed to come in and defend. The petition alleges that the company was never indebted to Beattie in any sum, and that the two notes on which the Beattie action was based were given without any consideration whatever. It is further alleged that the total indebtedness of the company does not exceed the sum of \$12,000 as shown by its annual report of 1908, which was signed by Mr. Beattie as a director of the company.

The annual report of the Butte Coalition Company for the year 1908 has recently been made public. There were produced, during the year, 264,031 tons of ore, 18,521,282 pounds of copper, 300,192 oz. of silver, and 1831 oz. of gold. A total of 900 men are employed by the company.

The Great Northern Railway has recently issued a new tariff on ore rates between the principal shipping points in the State. The tariff is made retroactive and dates from April 27, so that all ore shipments made since that time are subject to rebates. A change is made in the basis of ore valuation, the new schedule classifying all ores exceeding \$100 valuation at the \$100 rate, instead of adding 20 per cent to the rate for each \$50 increase. It is expected that the re-

sult will be a material benefit to the shipper.

At the annual meeting of stockholders of the Reins Copper Company held in this city a few days since the following directors were elected: J. M. Guffey, T. N. Barnsdall, John H. Gailey, William P. De Armit, F. W. Marland, W. F. Johnson, George D. Prentice, A. P. Childs, Augustus Hartje, all of Pittsburgh; John P. Reins and Glenn L. Thompson, of Butte.

Denver

June 11.—The monthly measurement of the work performed under the Carlton contract at the Roosevelt deep drainage tunnel in the Cripple Creek district shows a total distance driven during May of 954 ft. At the north heading from the intermediate shaft 290 ft. were driven and at the south heading 262 ft. The portal heading was driven 402 ft., bringing the total distance from portal to breast up to 6288 ft., and the total distance covered in all three headings to date is 9378 ft. On June 1 there remained 227 ft. between the south heading of the intermediate shaft and the portal heading and it was expected that the connection will be made about the middle of June. During the last 15 days of May the picked crew in the portal heading drove the tunnel 246 ft. or at the rate of over 16.4 ft. per day. In this work there was used a new model machine, in which three Leyner drills were set up on a bar at the breast of the tunnel.

At the recent annual meeting of the Gold Dollar Consolidated Gold Mining Company at Cheyenne, the present management was sustained and H. L. Shepherd, of Cripple Creek, was re-elected president, with other officers and directors as follows: A. E. Carlton, treasurer; J. R. Young, secretary; E. E. Quentin and J. W. Hughes, directors. Of the 2,068,000 shares represented at the meeting, it is stated that the opposing faction controlled only 308,000, notwithstanding the fact that circular letters had been issued some time since making violent attacks upon the Carlton management. Announcement was made that the company will continue the regular payment of quarterly dividends of 1/2c. per share.

According to reports from London, the April production of Stratton's Independence mine was 2263 tons of an average value of \$22.75. There were treated at the company's dump mill during the same period 3700 tons. No figures, however, are given of the average value of this dump rock, but the profits accruing to the company from "both mining and milling departments" was \$11,390.

One shipment from Silverton for May aggregated 4525 tons, 150 tons being high-grade crude ore and the balance concentrates. The total would have been close to 6000 tons, if it had not been for the fire at the Gold King mine. The mine buildings which were burned about the

middle of May will be replaced by modern steel structures. Repairs are being made on the aerial tram and when these are finished, temporary quarters will be provided for the men and work resumed in the mine. It is stated that the mine was in excellent condition at the time of the fire.

At a meeting of the Portland Gold Mining Company on June 9, it was announced that construction of a 300-ton cyanide mill at the mine near Victor will be commenced at once, and it is hoped will be ready for operation by the end of the year. The low-grade ore from the mine and the immense dumps will be treated, and it is stated that the experimental tests have shown that \$2 ore can be treated at a profit. At the Isabella, which also has its cyanide mill at the mine, it is also stated that \$2 ore is being treated successfully, and that during the past month they treated daily 125 tons of the above value, and that the bar sent to the Denver mint was worth \$7500.

The Moose mine which produced half a million in the early days of Cripple Creek, and has been practically abandoned for years owing to the gas in the workings, is now going to be made capable of exploration for new orebodies. A connection will be made with the 1000-ft. level of the Cresson company, which has taken a bond and lease on it.

Indianapolis

June 14.—There was, during the past week, greater buying for both manufacturing and storing purposes. It is understood that the requirements of the railroads were such as to put into service nearly all of the empty cars. Orders for later delivery are being placed more freely and numerous inquiries are received as to prices and facilities for immediate and future shipments. Operators say the reports from leading industries are favorable.

The retail coal dealers of Indiana are stocking up more than usual. The prices at the mines have not been increased, but there are indications of a raise July 1. The retail dealers have announced a strictly cash basis on which prices have been cut 15 to 20 per cent. in order to induce consumers to lay fuel.

Oklahoma

June 12.—Secretary of the Interior Ballinger has prepared new regulations governing oil and gas-pipe lines in Oklahoma, and will make them public soon. Meantime he announces that the point of the changes consists in eliminating from the regulations the "common-carrier clause" and the so-called "confiscatory clause." These changes have undoubtedly been under consideration at the department for some time, but they were not made until a public hearing was given to representatives of all of the pipe-line companies operating in Oklahoma, to the Mid-Continent Oil

Producers' Association and others. The "common-carrier" clause in the old regulations seemed to be no longer necessary because of the fact that the new State of Oklahoma has passed an act fully covering the subject, and because more than 70 per cent. of the oil-producing land in Oklahoma has been taken out of the control of the Department by the act which removed restrictions from the Indian lands, and which went into effect July 27 last. The so-called confiscatory clause in the old regulations permitted the Secretary to cancel a grant to a pipe-line company if it violated any of the regulations of the Department. With this clause out, the question of the pipe-line's violation of regulations and law and a forfeiture of its franchise will be left to the courts to determine. The capacity of pipe lines operating in Oklahoma has proved wholly inadequate to handle the product, and this condition has existed for some years. Only about 50 or 60 per cent. of the production is handled by the present pipe-line companies. As a consequence more than 55,000,000 bbl. of oil have been stored in the field and much oil is going to waste. No new companies have recently ventured in the field on account of the two clauses in the regulations.

Salt Lake City

June 10.—The production of coal is becoming one of Utah's most important industries. The report of E. W. Parker, of the U. S. Geological Survey, shows the total production for 1908 to be 1,848,792 short tons, having a value of \$3,119,338. Although the coal production decreased in sympathy with the general business depression throughout the country, an increase is reported in the value of the product. The report shows that 2664 men are employed in the mines. The areas in Utah known to contain workable beds of coal are estimated by M. R. Campbell, of the Survey to aggregate 13,130 sq.m., and there are in addition 2000 sq.m. of which little is known, but which may contain workable coal beds. The original contents of these fields are estimated by Mr. Campbell to have been 196,458,000,000 short tons of coal. The total production since mining began in 1870 to the close of 1908 has amounted to 20,683,974 short tons. On the basis of one-half ton wasted for every ton of coal mined and marketed, the exhaustion during this period has amounted approximately to 31,000,000 short tons, or 0.016 per cent. of the original supply.

The new Tooele Valley railroad, the line that connects the International Smelting and Refining Company's smelter site at the mouth of Pine cañon, was opened to traffic on June 10, the first train consisting of five cars of cement, lumber and other material for the new plant. Now that this road is opened the work on the smelter will progress rapidly.

The shipments from the Tintic district

during the week ending June 4 amounted to 219 cars of ore, and of this number 96 cars were of 50-ton capacity. The other cars were of 20-ton capacity. The output follows: In small cars, Iron Blossom, 38; Brooklyn, 1; Colorado, 31; Beck Tunnel, 6; Dragon Iron, 33; Black Jack, 2; Swansea, 2. Large cars, Ajax, 1; Grand Central, 6; Lower Mammoth, 1; Victor Consolidated, 1; Sioux Consolidated, 14; Iron Blossom, 2; Yankee Consolidated, 2; Bullion Beck, 3; May Day (crude ore), 6; May Day (concentrates), 2; Centennial Eureka, 42; Eureka hill, 4; Mammoth, 10.

Goldfield, Nevada

June 8—Figures compiled by the Goldfield Mine Owners Association regarding the number of men working in the mines of the district, show 1065 men employed, exclusive of salaried employes of the various companies, which would increase the number about 250. In addition there are a number of properties being worked by the individual owners who would not appear in the total as given above.

State Mine Inspector Stuart and Deputy Inspector Ryan have completed their inspection of the Goldfield mines and report favorably on the methods employed, both on surface and underground, for the protection and safety of employees. Particular comment is made concerning the Consolidated and Florence properties, where the unusually large stopes are extremely well timbered and every precaution taken for the avoidance of accidents.

H. P. Henderson, superintendent, gives the following estimate of production of the Goldfield Consolidated for the month of May: Total tons extracted, 21,305; total extraction, \$707,000; total cost, \$145,500; estimated profits, \$622,000. The Mohawk and Jumbo claims are producing about 8000 tons per month of \$35 average value. The Red Top and Lucky Boy claims from 6000 to 7000 tons per month, averaging \$37 and the Combination about the same amount averaging \$45 per ton.

Cobalt

June 12—The Coniagas Mines, Ltd., are going to prospect more thoroughly the southeast corner of the property underground. Work is being started in the old shaft in the center of the town, and it is being pumped out preparatory to sinking. It is now down 18 ft. on a calcite stringer giving low values in silver.

A 25-h.p. plant has been installed at the Eastborne mine. This will be used to carry on development. The shaft, which is now down 40 ft., will be sunk an additional 75 ft. and crosscuts run to prospect the property. There are two small veins showing in the bottom of the shaft, but no values have been found as yet. The Silver Lode mine, adjoining the King Edward, has started up again.

In an upraise 45 ft. above the 150-ft. level of the King Edward mine, No. 7 vein widened from a mere stringer to between 2 and 4 in. of high-grade ore. No. 7 vein runs parallel to No. 5 vein 200 ft. to the west on which a strike was made a few days ago. A prospecting tunnel is being driven into the hill from the side of Cross lake, but nothing of value has as yet been found. The mill is treating 20 tons per day.

No. 4 shaft of the Pan Silver is down 215 ft., and at the 200-ft. level a crosscut is being driven to strike No. 4 vein.

At the present time the Silver Cliff is doing development work on Nos. 1 and 2 veins only, and it is expected that these workings will be connected within the month. The company will not undertake any extensive work until the air from the Hydraulic company is ready for distribution.

In the crosscut at the 65-ft. level of the Silver Cross mine, 57 ft. to the north of No. 2 shaft a vein of calcite carrying small values in silver has been discovered.

At the 87-ft. level of the main shaft of the Michigan Cobalt a station is being cut, and a crosscut will be run to tap the vein on which the shaft was started.

The Gifford Extension is running a drift on the vein 100 ft. west of the main shaft at the 80-ft. level, but no silver values have been found as yet. The shaft will be continued to the 125-ft. level.

The Cobalt Hydraulic Compressed Air Company, which is putting in a 5000-h.p. plant at Ragged Chutes, on the Montreal river, to supply air to the mines of the Cobalt district, expects to have the power ready for distribution about Aug. 1. Considering the amount of work still to be done, however, it is doubtful if this will be possible. The pressure at the mines is to be 100 lb. For the larger consumers when six or more drills are used, the air will be supplied by meter; the smaller consumers using five drills or under will pay a flat rate depending on the number of drills in use. The following rates have been fixed by the Hydraulic company. For the large consumers buying by meter, 25c. per 1000 cu.ft. of air at 100 lb. pressure. For the smaller consumers, for one drill per 10-hour shift, \$5; 2 drills, \$4; 3 drills, \$3.50; 4 drills, \$3.13; 5 drills, \$2.80. This leaves a wide margin in favor of consumption by meter, and it is probable that before the contracts are finally signed, the mine managers will get together to compel the company to supply the power at a uniform rate.

A matter of great interest is at present before the shareholders of the Temiskaming & Hudson Bay mine. Many offers have been made for this property and, although none of these has been accepted, there is a general feeling among the shareholders that something should be done in order that they may have stock that is readily negotiable. At present the number of shares is so limited, there be-

ing only 7701 issued, and their value is so high, that they cannot be placed on the market and anything like their true value realized. A general meeting was called June 4 to discuss a proposition made by a broker. His idea is to form a new company to acquire the holdings of the Temiskaming & Hudson Bay, the capitalization to be from 3,500,000 to 5,000,000 shares of a par value of \$1. This stock is then to be handed over to the original company and sold through the brokers at about 75c. on the dollar. The matter was taken up at the general meeting and, although nothing definite was arrived at, it would not be surprising if some action were taken in the near future. The company will pay another dividend at an early date.

The Nancy Helen mine has closed down, but prospecting will be continued with the aid of a diamond drill. It is understood that an offer by a New York firm of \$4,000,000 for the O'Brien mine has been turned down. The Hargraves mine is running two drills in the shaft and one in the drift. The shaft has reached a depth of 275 ft.; at this point a station will be cut and a crosscut started. Some work has been done at the 70- and 175-ft. levels, but so far ore has not been struck.

The new vein recently found at the Beaver has turned at an angle with its general direction and the ore has disappeared. This is a common occurrence, however, in this locality and the management confidently expects to get the ore again in a short time.

Mexico

The new freight rates on coal and coke on Mexican railroads went into effect on June 1. It is claimed that these rates will keep at home fully \$5,000,000 annually that has heretofore gone out of the country.

The coal mines of the state of Coahuila, by new methods of cleaning and washing coal and the development of new coal measures, are now prepared to furnish coal and coke over the republic. Several years ago when Mexico could not supply the demand for those two important fuel staples the railroads adopted coal and coke rates which greatly favored the foreign product. During the last six years a wonderful development of the coal resources of Mexico has been steadily in progress, and now the coalmen can justly claim they are prepared to supply the trade. The railroads have been brought to a realization of the fact that the rates on the foreign coals which have prevailed on the roads for years have discriminated against the native product. The new rates equalize the matter. There is no favoritism of rates shown now to ports of entry as against rates from internal points. Mexico has no important duty on coal and coke.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alabama

JEFFERSON COUNTY

Tennessee Coal, Iron and Railroad Company—Four of the open-hearth steel furnaces at Ensley have been started, and the rail mill has also been put in operation. There is sufficient pig iron on hand to run the furnaces for three or four weeks. Two blast furnaces are ready and will be blown in before that time if conditions warrant.

Williamson Iron Company—The blast furnace at Birmingham has blown out for repairs. It is a small furnace.

Arizona

COCHISE COUNTY

Tombstone Consolidated—The shaft is flooded as a result of an accident to the boilers. The management expects to control the water within a few days. It is reported that a duplicate set of pumps will be installed.

Denn-Arizona—Ore has been encountered on the 1250-ft. level. It is native copper in limestone.

Bisbee Coalition—The Bisbee Coalition Mining Company has been organized to absorb the North Bisbee Development Company, by buying the North Bisbee stock at the rate of one share of Coalition for one share of North Bisbee. The new company is capitalized at 1,000,000 shares at \$2 each, and it has been arranged that 150,000 shares are to be sold on the New York market at par.

GILA COUNTY

Miami—About 13,500,000 tons of ore have been developed since the beginning of actual work. A large body of ore is now being blocked out above the 370-ft. level preparatory to mining.

GRAHAM COUNTY

Arizona Copper—The output for the month of May was 2,854,000 lb. of copper.

Shannon—The May production of copper was 1,556,000, lb. being an increase of 98,000 lb. for the corresponding month last year. The total for five months this year is 7,988,000 pounds.

MARICOPA COUNTY

Vulture—At the annual meeting of stockholders of the Vulture Mines Company, the entire board of directors was re-elected as follows: Frank P. Estabrook, Joseph B. Locke, I. M. Taylor, Frederick W. Rockwell, Edward T. Frisbie, Robert Mackay and J. Winslow Pierce.

PINAL COUNTY

Gila Copper—Authorized capital stock, 1,000,000 shares; outstanding, 550,000 shares; treasury, 450,000; par value, \$10. Of the treasury stock 55,000 shares have been offered to the present stockholders at \$2.50 per share, most of which has been taken. Cash in treasury \$75,000; no debts. The property has been developed by 3000 ft. of underground workings, and 6350 ft. of churn drilling. S. W. Mudd is chairman of the executive committee, and Philip Wiseman is manager. The property is seven miles from Kelvin.

California

ALAMEDA COUNTY

American Magnesite—A large gasoline-engine truck has been provided for hauling magnesite from the mines at Red Mountain to Livermore, for shipment to the Cummings factory at San Leandro.

BUTTE COUNTY

Gold Bank—Henry Descant, of San Francisco, has bonded the Gold Bank and Gold Queen quartz mines, at Forbestown, and will work them through the Gold Bank tunnel.

Indiana Gold Dredging—The dredge, wrecked during high waters of last winter, has been righted and pumped out and the machinery repaired.

Steifer—Litigation over this property having ended, construction and development will begin at once.

KERN COUNTY

Desert—Several strong veins have been opened, and it is expected that a 20-stamp mill will soon be erected. M. J. Monette, of Goldfield, Nev., and several Los Angeles people are owners.

Soledad—Litigation has been settled and the mine is now producing ore.

Queen Esther—This company, at Mohave, has bonded the Double Standard mine and good ore is being taken out.

MONO COUNTY

Golden Gate—Jos. A. Brown has sold this property to Mr. Edwards and associates of Bridgeport, \$40,000 to be paid July 4 for working purposes.

NEVADA COUNTY

Icompton—This mine, at Nevada City, is almost unwatered. The bottom of the 630-ft. shaft has been nearly reached.

Last of the Mohicans—James Morrison has purchased the controlling interest in

this Grass valley mine from A. and George Atterbury.

Ridge Tunnel—Williamson & Cole have discovered a rich ore shoot. The mine is near Washington.

Allison Ranch—This old and once productive mine may be again reopened, being under examination by Goldfield, Nev., men.

Pittsburg—Joseph Weisbein, president, is putting up an extensive surface plant. As soon as the water is all out, 10 machine drills will be put at work. Mark B. Kerr, Nevada City, is general manager.

PLUMAS COUNTY

California-Nevada Consolidated—A 6-ft. vein has been found. Anthony Lowe, of Prattville, is manager.

SAN BENITO COUNTY

Gold—Daniel Burg, of Pinosche valley, has discovered a ledge of gold-bearing quartz in that section. A small amount of silver is with the gold.

SAN BERNARDINO COUNTY

San Bernardino Borax Company—S. Riddel, James M. Kane and Isaac N. Thorne, of San Francisco, and J. W. Searles and Charles Gressard, of San Bernardino, have formed this company to mine for borax.

Borax Consolidated Company—This company has recently completed a borax-refining plant at Otis.

Colorado

BOULDER COUNTY

Alton Tunnel—Manager J. Burke, of Cardinal, Colo., announces that the company intends building a concentrating plant during the year.

London Gold and Copper—Kansas people are interested in this organization, to operate the London and the London Extension mines, near Gold lake, east of Ward, and a 250-ft. tunnel contract has been let.

CLEAR CREEK COUNTY

Atlantic and Daily Districts—E. M. Moscript and associates, of Idaho Springs, are building a mill to handle their own and custom ores from these districts. It is stated that the Atlantic Mining and Milling Company contemplates driving a 5000-ft. adit. C. B. Ireland, Georgetown, Colo., is manager. Ore has been opened in the Coffin mine on Young mountain.

It carries gold, silver and lead, and is of smelting grade.

Vidler Tunnel—Work is to be resumed on the big bore as soon as the electric line for the operation of the compressor plant is finished. The tunnel is in 4300 ft., and about 2200 ft. farther will connect with the tunnel from the western side, near Argentine.

Drives-Pelicon—Louisville people interested in these mines at Silver Plume have appointed J. H. Robeson as manager, and active developments will be carried out under him.

GILPIN COUNTY

Gilpin-Boulder Consolidated—A gasoline hoisting plant is being installed, an addition being built to the shaft building, and arrangements made for sinking the Poole shaft several hundred feet deeper; machine drills and compressor may be installed. W. H. Crabtree, Central City, Colo., is superintendent.

Argosy—Denver and Philadelphia people, interested in the Maud S. mine of this company in the Russell district, will install machinery and erect a new shaft building. Joseph Hesselbline, Central City, Colo., manager.

Union Glanders—George S. Petteway, of Florida, has taken a four years' lease and bond on this property in Russell and Lower Fall River districts.

Medora—Arrangements have been made with the Penobscot company to drive a lateral from its tunnel, and more equipment is to be installed by Manager J. W. Koons, Rollinsville, Colorado.

Free Gold—F. A. Burnell, of Denver, has opened up a 5-ft. vein of milling ore, and will treat the same at the Daisy mill, which he has leased. Machinery is to be installed at the shaft, and a new engine and boiler has been installed in the Daisy mill. J. Bechtold, Rollinsville, Colo., is superintendent.

Town Topics—*A lis pendens* has been brought in the Circuit court asking that the sale of the East Notaway property of this company by public trustee to Rufus J. Foster for \$24,272 to be declared null and void; also asking for a receivership during the proceedings. Eastern stockholders are the applicants.

Perigo—Smelting ore is being shipped to the sampling works and mill concentrates are also being regularly produced. D. C. Earl, Rollinsville, Colo., is superintendent.

LAKE COUNTY

Progressive—The Cady Mining Company has leased this property on North Fryer hill to Al. Gans and associates. The shaft will be repaired and new machinery installed, including heavier pumps. The shaft is 300 ft. deep, and from this point exploration will be carried on by drifting. The work is in charge of C. W. Rogers.

Castle Pierre—An output of 25 tons daily is being sent from this Carbonate hill property to the local smelter. Preparations are being made to operate the Evelyn, Giant, etc., from the Castle View shaft, these claims being under lease to the same people.

Lou Dillon—The tunnel started a few months ago is now in 200 ft., and the breast shows several streaks of lead ore. A shaft is also being sunk farther south.

Tribune—The vein of gold ore recently discovered on this property has been drifted on for a distance of about 40 ft., and a shipment will soon be sent to the smelter.

Jennie June—With the disappearance of snow in the Tennessee district this mine will resume active operations. Work is to be carried on at the 250-ft. level, from which high-grade gold ore was obtained last season.

Yak Tunnel—The breast of the main tunnel is now nearly opposite the New Monarch shaft and is nearing the 4-mile mark. Good progress is being made in driving the lateral to the Resurrection No. 1 property.

Sunday Tunnel—Shipments are being sent regularly from this property to the local smelter, the output being about 30 tons daily.

ROUTT COUNTY

Snake River Consolidated—This company is reported to have opened up milling ores in its property, near Three Forks, and is considering the erection of a mill. Lewis A. Pease, Steamboat Springs, Colo., is manager.

Idaho

SHOSHONE COUNTY

Standard—A large body of rich ore was encountered recently on the 1650-ft. level. It is reported as being better than on the upper levels.

Skookum—W. M. Bacon has been given judgment in the District court against Kennedy Hanley and his wife for \$49,659 with costs and interest amounting to \$51,856. In the Superior court of Spokane county, Wash., Aug. 24, 1908, suit was instituted against Mr. Hanley and judgment of \$55,695 granted against him in March, 1909. Of this sum \$6000 is alleged to have been paid. The defendants are owners of property in Shoshone county, including one-eighth interest in the Skookum mining claim. The removal of ore from this claim was the cause of the suit.

Indiana

Hudson Mine Company—The Terre Haute Trust Company has brought suit for the appointment of a receiver for this company, on behalf of Chicago men, who hold \$40,000 in bonds issued by the company when it bought the mine. The new

company had not long been owners when a strike began, which continued for a long time and ultimately involved President Lewis, of the Mine Workers, in a serious controversy with the Indiana officials. The Operators' Association backed up the mineowners in the exacting of fines against idle men under provisions of the yearly agreement. Suits were brought to recover these fines and other wages, and were successful. Other financial difficulties arose and a receivership was decided upon. It is expected that an early adjudication of the company's affairs will be made and perhaps a change in ownership of the mine will also occur.

BLACKFORD COUNTY

More oil wells are being drilled than ever before. In one week recently nine new wells were brought in and two dry holes reported. The seven producers turned out 280 bbl. per day, the heaviest well producing 70 bbl. One heavy-pressure gas well was completed.

GIBSON COUNTY

District Vice-President Rollins, of the miners' union, spent a portion of last week in this county endeavoring to settle differences between local miners and the Princeton Coal Mining Company over the shot-firing question. This question seems to be a difficult one to settle. Formerly the miners employed their own shot-firers. Then the employment of them was turned over to the company, and now, it is said, the men again want to employ their own shot-firers while the company wishes to continue.

VIGO COUNTY

A fire started June 3 in the Fairview mine belonging to the Carlisle Coal Company, a few miles north of Carlisle. The fire is said to have been started by a windy shot.

Kentucky

JOHNSON COUNTY

Consolidation Coal Company—This company is preparing to develop its property in the Miller's Creek coalfield. A large mining plant will be installed, mines opened and a railroad built to connect with the Chesapeake & Ohio. The new work is under charge of L. L. Malone, of Fairmont, W. Va., as manager.

Louisiana

The production of petroleum in May was 265,230 bbl., an increase of 866 bbl. over April. The shipments were by rail, 90,652 bbl.; by Butte la Rose pipe-line, 23,973; total, 114,625 bbl., or 103,868 bbl. less than in April. Refinery consumption is estimated at 50,000 bbl.; field consumption at 15,000 bbl. There were 20 wells completed in May, of which 13 were oil producers, 2 gas producers and 5 dry. On May 31 there were 49 wells under the drill.

Michigan

COPPER

The estimated output of copper for the Lake Superior district during the month of May is 19,917,500 lb., as compared with 19,675,500 lb. for May, 1907. The total for first five months of this year is 95,342,800 pounds.

Calumet & Hecla—About July 1, the offices of all the subsidiary companies will be transferred to the main office at Ashburton Place, Boston. The transfer will include the Osceola, Tamarack, Ahmeek, Isle Royale, Seneca and Larium, the offices of which have been in the Sears building. The offices of the Centennial and Allouez will be transferred from State street to Ashburton Place, also. It is reported that the office forces of these companies will be retained.

North Lake—This company has encountered ore in its No. 3 drill hole at a depth of about 1800 ft., which is the approximated position of the Lake lode.

New Bottic Exploration—No. 2 drill hole has been started to the west of the first one. No. 1 hole was put down vertically to tap the various formations opened by the trench; but, evidently due to a faulting of the formation, the expected results were not revealed.

Mass—The first mill run on the new lode has been completed. The rock came from the opening of the drifts at the 17th level and consisted of about 600 tons, which yielded about 20 lb. mineral to the ton.

IRON—MARQUETTE RANGE

Empire—This mine, in the Cascade district, is being actively worked and the force has recently been increased. It is owned by M. A. Hanna & Co., of Cleveland.

Empire—Oglebay, Norton & Co. have added to the working force, and expect to make good shipments this season.

Volunteer—This property is being tested with diamond drills.

IRON—MENOMINEE RANGE

Cystal Falls District—It is stated that Corrigan, McKinney & Co. are preparing to ship the big stock piles accumulated at the Dunn, Great Western and Tobin mines.

Iron River District—Active exploration work and shaft sinking are going on north of Iron river, on the James, the Konwinsky, the Hector, the Hall and the Barnette tracts.

Montana

BUTTE DISTRICT

Davis-Daly—The Colorado shaft has reached a depth of 1485 ft. Preparations are now being made to sink to the 2000-ft. level. One hundred men are employed.

BROADWATER COUNTY

Ohio-Keating—At the recent meeting of stockholders the following directors were elected for the ensuing year: R. M. Calkins, W. H. Penfield, C. H. Smith, George M. Bourquin and John F. Cowan. At the directors' meeting held afterward, R. M. Calkins was elected president, and C. H. Smith, secretary and treasurer.

FERGUS COUNTY

West Kendall Gold Mining Company—The company has recently been incorporated by F. J. Robinson, C. A. Drinkard and J. H. Connely. The capitalization is \$1,000,000; par value of shares is \$1 each. The company will develop what is known as the McClure group of claims on the west side of North Moccasin mountain. The ore is free milling.

GALLATIN COUNTY

Washer Copper—The coal washer of the company, situated at Stoops and valued at \$200,000, was recently destroyed by fire, presumably of incendiary origin. Edwin G. Bartel and Dr. J. P. Reins, of Butte, had recently secured a lease on the property from the Washoe company. Previous to that time the plant had been idle for some time.

JEFFERSON COUNTY

Corbin-Clancy Creek Mining Company—The company has recently been organized by Jack O'Neil, D. W. Rodgers and Meyer Gansberger, of Butte. Its capital stock is \$100,000; par value of shares is \$1. The company owns the Ariadana and Bee quartz claims, situated at Gregory gulch, west of the Corbin & Calumet property. Men have recently been put to work cleaning out the 700-ft. tunnel. W. C. Hoskins is in charge of the work.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Black Butte—The miners have leased the workings opened by the main shaft and are operating the same on a coöperative plan. Small shipments are being made from the property.

Pittsburg-Nevada-Rialto—A consolidation has recently been effected, and last week two shifts were started on the property of the Pittsburg-Nevada, situated on the south slope of Knickerbocker mountain, about three and one-half miles east of Goldfield.

Nevada Eagles—The new shaft is down to a depth of 300 ft. The compressor and hoist, formerly in commission at the old shaft are being moved to the new shaft, which will be sunk to the 500-ft. level.

Yellow Tiger—Work has been closed down on this property for 30 days during which time arrangements are to be made for the resumption of work on a larger scale. Manager Maurice Starnes is now in

Denver to attend a meeting of the directors. It is expected that the shaft now 700 ft. deep will be sunk to the 1000-ft. point, at which depth the ledge, encountered in the upper levels, will be thoroughly prospected.

ESMERALDA COUNTY—RAWHIDE

There are 10 mines that can ship ore as soon as the mills are in operation: Grutt Balloon Hill, Mint, Marigold, Grutt Hill, Truitt, Dayton Toledo, Prosky No. 1, Rawhide Truitt, Miller, Morning Star, Kerns No. 2 and Kerns No. 1.

Mint Lease—The shaft is down to the 390-ft. level, and in a few days the cross-cut will be commenced on the 400-ft. level. The country rock in the shaft is the same as on the 150-ft. level where rich ore was found.

Grutt Balloon Hill Lease—During the past few days rich ore has been encountered on the 185-ft. level.

Kerns No. 1—This lease has been in litigation for some time, but all matters are adjusted, and the lease returned to its owners, W. B. Weddell and associates, of Ogden, Utah. It is the intention of the owners to push the work and cross-cut to the Prosky No. 1 vein.

Ellendale—A reported strike has been made 30 miles east of Tonopah in the Salisbury wash. The district is called Ellendale. The ore at the surface runs high in gold.

Golden Arrow—It is the purpose of the leasing company to sink to the 500-ft. level before any crosscutting is commenced. The shaft is now 300 ft. deep. Dr. Gordon is the principal financier of the company. The lease is located on the Rawhide Consolidated property.

Dayton-Toledo—This lease on the Coalition estate is now shipping much ore to the small mills on the flat east of Rawhide. The shaft is now down 300 feet.

Marigold—Shipments from this lease for the last two weeks in May exceeded \$12,000, the ore being taken from the north and south drifts on the 160-ft. level.

Prosky No. 1—An eight-ton shipment was made last week to the Western Ore Purchasing Company at Hazen, the ore coming from the 100-ft. level. The shaft now 100 ft. deep is being sunk to the 150-ft. level.

Victor Lease—General manager I. H. Cook, of Rawhide, is preparing for the installation of a ten-stamp mill. The company claims to have 20,000 tons of \$12 ore blocked out on the 125- and 200-ft. levels.

ESMERALDA COUNTY—WILD HORSE CAÑON

Rogers Brothers—Work will soon commence on the Wild Horse Cañon property, 22 miles south of Rawhide, owned by the Rogers Brothers, of Chicago. They are now preparing to install a large hoist and compressor on their group of claims.

New York**DUTCHESS COUNTY**

American Cement Company—This company has bought 13 acres of land on the river front at Poughkeepsie for the purpose of building a large portland cement plant. It has also bought a large tract of land near that city, on which there are deposits of limestone.

Oklahoma

In the month of May, according to the reports of the *Oil Investor's Journal*, 284 new wells were completed in the Mid-Continent oil districts; of which 255 were oil producers and 29 were dry. There were 207 new wells in progress at the end of the month.

The production of petroleum in May, as reported by the same authority, was 3,532,596 bbl., or 208,702 bbl. more than in April. The shipments in May were 3,374,396 bbl., leaving 157,700 bbl. to be added to stock. The total stocks reported in Oklahoma on June 1 were 55,393,756 bbl. crude oil.

JOHNSTON COUNTY

Chickasha Mineral, Oil and Silica Company—This company has been formed by the consolidation of the Oswald, Kemp & Lewis Silica and the Lytton Mineral companies. Its object is to develop extensive glass-sand deposits near Tishomingo. T. W. Lytton is president and E. D. Reed, secretary and treasurer.

TULSA COUNTY

Brummett Coal Company—This company at Tulsa is preparing to make improvements to its plant. It will build a switch from the main line of the St. Louis & San Francisco railroad to the mine; it will also install an electric mining plant with a daily capacity of 200 or 300 tons. M. S. Stout, Tulsa, is president.

Oregon**DOUGLAS COUNTY**

A rich deposit of copper ore containing some gold is reported to have been found recently about eight miles south of Roseburg. The mineral outcrops at the surface a distance of 600 ft. and the vein is from 50 to 60 ft. wide.

LANE COUNTY

Nicodemus Mining Company—This is a newly organized company that has acquired the Star Consolidated Mining Company of Bohemia, with a capitalization of \$20,000. One-half of the stock has been sold at par, and the balance will be sold from time to time as money is needed for development work. The officers are Dr. R. G. Black, president; H. G. Colton, vice-president; Charles H. Thompson, secretary and treasurer. All are Portland men.

Twin Rocks—Development work has been resumed. The long cross-cut tunnel

will be completed to the ledge, and then the management plans to install a plant. Louis Hartley, of Bohemia, Ore., is manager.

South Dakota**LAWRENCE COUNTY**

The mining situation in this section of the Black Hills has improved considerably since the flood of last week. Unusually heavy rains continue to render ore shipments uncertain.

Mogul—The mines ship to the mill over the Burlington while repairing the narrow-gauge. The mill is operating at three-quarters capacity.

Golden Reward—Operations will be resumed this week. The shut-down was due to the recent flood.

Homestake—Mining was suspended a few days, but the plant is now running at full capacity.

Reliance—The flood carried away the new tailings dam which will prevent resumption for some time as the company has been restrained from discharging tailings into Little Spearfish creek.

Minnesota Mines—A second low-speed Chilean mill has been installed which will increase the milling capacity from 100 to 200 tons per day. In order to provide this increased tonnage, tracks are being laid from two open cuts to the mill and a 12-drill compressor is being installed.

Texas

Oil production in the southeast or coast districts in May was 822,225 bbl., an increase of 59,585 bbl. over April. Shipments by sea were 289,253 bbl.; by rail, 478,871; total, 768,124 bbl., or 171,826 bbl. more than in April. Refinery consumption is estimated at 150,000; field consumption at 60,000 bbl. There were 52 new wells completed in May, of which 36 were oil producers and 16 dry. There were 67 new wells in progress at the end of the month.

Utah**BEAVER COUNTY**

Cedar-Talisman—This property in the North Star district will soon be on the shipping list. It is planned to haul the ore to Milford for shipment to the Salt Lake valley smelters. S. S. Pond, General manager, Beaver, Utah.

JUAB COUNTY

Beck Tunnel—The annual meeting of this company was held in Provo last week, all the old officers, including Jesse Knight, president and general manager, being re-elected. During the year a total footage of 3550 ft. was driven. The report explains the work that is being done to recover the faulted orebody from which \$675,000 in dividends were paid.

Tint's Mines—This company, which was

recently organized to work the Bradley group of 30 claims in northwest Tintie, is making good headway. The company is also working the American Star group, covering the extension of the Grand Central-Mammoth ore-bearing channel. M. F. Shannon, superintendent, Eureka, Utah.

Sioux Consolidated—The new compressor is now in use. It is of five-drill capacity, and will enable the company to do considerable prospecting in addition to handling the usual amount of ore. The orebody has been opened in such a manner that a steady output of about 14 carloads per week is being maintained.

SALT LAKE COUNTY

Columbus Consolidated—The big station pump is ready for operation, and will be put in use whenever required. The management is now drifting east on the 400 level. The aerial tramway while out of commission was replaced by teams, but is again in working order.

Washington**KING COUNTY**

Grand Ridge Coal—After several weeks' preparatory work regular shipments are being made to Seattle. This mine has been idle for a number of years.

SNOHOMISH COUNTY

Nonpareil Consolidated—The second ledge in the crosscut tunnel has been cut, showing 7 ft. of chalcopryite.

Index Granite Works—This company is now employing 128 men. A tunnel is being run to the lower quarry.

Wisconsin**IRON-GEOGRAPHIC RANGE**

Germania—At this mine, formerly the Harmony, Hayes Brothers have resumed work. The mine is being unwatered and the shaft repaired.

ZINC-LEAD DISTRICT

At Platteville all the mills are now in operation, and the improvement in the ore market has brought about the reopening of all the mines in the vicinity. At Benton also there is much activity for the same reason.

Culvert—Madison, Wis., people have bought this mine, which adjoins the Frontier, and is supposed to carry the extension of the rich orebody found in that mine. The new owners will open up the mine and equip it with a mill.

Fox—Another shaft is to be sunk to improve the ventilation. The mine is making a large output, the mill making 33 tons of concentrates daily.

Mills—This mine has been shut down, pending a reorganization of the company.

Pandercenter—The new rotary roaster is in operation and is producing a high-grade of jack. It recently turned out 105 tons of mill concentrates from 345 tons of rock, a result of over 30 per cent

Canada

BRITISH COLUMBIA—EAST KOOTENAY

Hosmer Mines, Ltd.—The main entry (a cross-cut tunnel) of the Hosmer coal mine, Crow's Nest Pass, is in about 4250 ft., in which distance it has intersected nine seams of coal. Its total section is 22 ft. by 7 ft. 6 in., and it is divided into three compartments—two haulage-ways and a man-way. The present equipment of the colliery is for an output up to 2000 tons of coal a day.

Corbin Coal Mines, Ltd.—This company is opening a coal mine up the south fork of Michel creek, 13 miles from McGillivray station on the Crow's Nest Pass branch.

ONTARIO—COBALT

Ore Shipments—Shipments of ore from Cobalt for the week ended June 5 were: Coniagas, 126,410 lb.; Crown Reserve, 120,613; Cobalt Central, 59,650; Kerr Lake, 62,125; La Rose, 239,128; McKinley-Darragh, 59,460; Nipissing, 325,715; Silver Queen, 127,470; Temiskaming, 60,000; Tretheway, 127,000; total, 1,307,571 pounds.

Chambers-Ferland—The statement presented at the annual meeting on June 9 showed cash in bank, \$54,799; value of ore in transit and at smelters, \$21,544; value of ore on hand, \$15,257. The active liabilities were \$14,324 in all.

Kerr Lake—The output for May is reported at 200,000 oz. silver. The main drift on No. 7 vein on the 150-ft. level was run for 72 ft. on a continuous pay streak, averaging 10 in. in width of high-grade ore. A new vein showing good silver contents has been struck by trenching on the east side of the property.

O'Brien—A vein found some time since on the surface near No. 16 shaft has recently been tapped underground by a crosscut driven at the 110-ft. level. It is about 7½ in. wide.

Temiskaming & Hudson Bay—At a meeting held at New Liskeard, Ont., June 4, the stockholders voted to increase the capital stock from \$25,000 to \$350,000. Of the new stock \$250,000 will be distributed to the present shareholders, each of whom will receive \$100 for \$1 of his present holdings. The remaining stock will be used for the erection of a concentrator at the plant on the most northerly lot of the company where the mine is at present, and the development of the south end of the property. The increase of the stock was delayed until the disputes with the government were settled and a patent finally issued for the property.

Trinity Cobalt—An order has been granted by the court in Toronto for the winding up of this company on petition of Henry E. Juening, of Buffalo, a creditor for \$8180. The company was incorporated in May last, with nominal

capital of \$100,000. The company is located at Haileybury.

ONTARIO—GOWGANDA

Bartlett—The first shipment of ore consisting of 3000 lb. of high-grade has been made by canoe over the water route to Latchford. The compressor plant is ready for operation.

ONTARIO—SOUTH LORRAIN

Wettlanfer—Frank Loring, consulting engineer, states that \$15,000 worth of silver ore has been taken out of the shaft, which is now 60 ft. down, the showing of silver increasing with depth. A five-drill compressor with two 60-h.p. boilers is in course of installation. Thirty men are at work under Superintendent A. C. Bailey.

ONTARIO—WELLAND DISTRICT

Provincial Gas Company—The attempts to obtain gas or oil in the marsh south of Welland, at a cost of about \$25,000, have resulted in failure. The latest venture was a well which was put down to a depth of over 3000 ft., without results.

QUEBEC

Amalgamated Asbestos Corporation—At the organization meeting held in Montreal, May 26, E. B. Greenshields was elected president; Hon. Robert Mackay, first vice-president; H. E. Mitchell, second vice-president; R. H. Martin, general manager. Offices have been taken in the Eastern Township Bank building, Montreal. The various properties purchased were transferred on June 1 to the new company.

YUKON TERRITORY

The complaint that the freight rates on the White Pass & Yukon railway are excessive, preferred by the Dawson Board of Trade, was brought before the Canadian Railway Commission at Ottawa, June 9. F. T. Congdon, M. P. for the Yukon, represented the complainants. He contended that the present freight rates were so high that they were absolutely prohibitive to the exportation of ore, and that, if they were lowered an enormous trade would be developed. The railway, he said, had been represented as costing \$8,300,000, whereas the actual cost was \$5,000,000, which was excessive for 120 miles. The books of the construction company, he charged, had been purposely destroyed. F. H. Chrysler appeared for the railway. The case was continued.

Yukon Gold—The ditch is now being operated at half capacity. An extension of 10 miles will be made this summer to Gold hill, and the entire line, 70 miles long, will be completed and in operation for mining work next spring. The first work done with this water has been in Lovett gulch. Seven large electric dredges are in operation.

Mexico

CHIHUAHUA

Dolores—The last monthly shipment consisted of 52 bars gold-silver bullion valued at 105,000 pesos.

International Gold Mines Company—It is planned to increase the output as well as the scope of development operations. Shipments of high-grade concentrates are being made. J. H. Pender is manager.

La Fortuna—Shipments of high-grade silver ore are being made from this company's Santa Maria mine in the Neuva Casas Grandes section in the northern part of the state.

San Toy—The work of building a new steel tram terminal station, replacing the wooden structure lately burned down, is now under way, and on its completion the output will be increased.

Yoqueivo—High-grade gold ore is being sent out in carload lots from this mine in the Rayon district. The present working force is about 150 men. Qualey Brothers, of New York and Chihuahua, are the owners and operators.

Africa

TRANSVAAL

Gold production in the Transvaal in May is reported at 634,498 oz. fine, being 17,397 oz. more than in April. For the five months ended May 31 the total was 2,824,984 oz. in 1908, and 3,019,430 oz.—or \$62,411,618—in 1909; an increase of 194,446 oz., or \$4,019,200, this year.

Asia

INDIA—MYSORE

Kolar Goldfield—Gold production in May was 46,514 oz. bullion, being 386 oz. more than in April. For the five months ended May 31 the total was 226,114 oz. bullion in 1908, and 227,650 oz. in 1909; an increase of 1536 oz. The bullion reported this year was equal to \$4,234,973, or 204,885 oz. fine gold. The report includes two mines outside of the Kolar district proper—the Hutti Nizam and the Dharwar reefs, in the Deccan.

Australia

NEW SOUTH WALES

Gold production in May was 13,041 oz. fine; for the five months ended May 31 the total was 90,153 oz., or \$1,863,467 in value.

WESTERN AUSTRALIA

Gold production in May is reported by the Chamber of Mines at 129,400 oz., being 8355 oz. less than in April. For the five months ended May 31 the total was 690,311 oz. in 1908, and 640,550 oz.—or \$13,426,200—in 1909; a decrease of 40,761 oz. this year.

New Zealand

Gold exports in May are reported by cable at 45,017 oz. bullion in 1908, and 46,525 oz. in 1909; an increase of 1508 oz. The bullion reported this year was equal to \$901,650, or 43,622 oz. fine gold. Exports of silver for the month were 164,635 oz. in 1908, and 175,058 oz. in 1909; an increase of 11,323 oz. this year.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, June 16—Little change in condition is to be reported this week. In the West the coal trade is improving slowly. Comparisons from week to week do not show very much change, but there is a great improvement over the corresponding date last year.

Very much the same conditions prevail in the Eastern bituminous trade. The business gains slowly, but still shows a marked advance over a year ago, which is reflected in heavier shipments from mines.

The anthracite trade is quiet and even, with no special feature, and few changes from week to week.

The injunction asked for against the proposed differential rates on West Virginia coal to Lake ports having been denied by the United States District Court, an appeal has been taken to the Circuit Court of Appeals by counsel for the Kanawha & Michigan Railroad Company.

The Commodities Clause—The following circular, dated June 1, shows the plan adopted by the Delaware & Hudson Company for complying with the commodities clause of the Interstate law. The Hudson Company is a subsidiary company, which was organized some time ago: "The Hudson Coal Company has this day arranged to purchase the entire present and future output of coal mined by the Delaware & Hudson Company. The Hudson Coal Company takes over and assumes all contracts and obligations incurred by the Delaware & Hudson Company to deliver coal, and is prepared to accept and fill orders for coal from the former patrons of the Delaware & Hudson Company."

It is reported that the Delaware, Lackawanna & Western will transfer its coal properties to a subsidiary coal company, the stock in which will be issued, in some form not yet determined, to the stockholders of the railroad company.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to June 5, short tons:

	1908.	1909.	Changes.
Anthracite.....	2,366,263	2,267,845	D. 98,408
Bituminous.....	13,781,818	14,913,686	1,131,868
Coke.....	2,332,808	4,246,566	1,913,757
Total.....	19,080,879	21,428,096	2,347,217

The total increase for the year to date was 12.3 per cent.

Coastwise shipments of coal from lead-

ing Atlantic ports, four months ended April 30, long tons:

	Anthracite.	Bitum.	Total.	PerCt.
New York.....	5,825,046	9,327,239	9,162,286	65.2
Philadelphia.....	758,976	1,391,440	2,150,416	16.3
Baltimore.....	85,227	1,125,498	1,211,655	8.7
Newport News.....		956,929	956,929	6.8
Norfolk.....		561,311	561,311	4.0
Total.....	6,666,249	7,366,347	14,032,596	100.0
Total, 1908.	6,208,427	7,137,567	13,375,994	

New York includes all the harbor shipping ports. The shipments at all ports include bunker coal for vessels in domestic trade. Total increase this year, 656,602 tons, or 4.9 per cent.

Coal tonnage passing through the Sault Ste. Marie canals, season to June 1, short tons:

	1908.	1909.	Changes.
Anthracite.....	146,061	260,060	1. 114,999
Bituminous.....	208,088	836,800	1. 628,712
Total.....	353,149	1,096,860	1. 743,711

The May shipments this year were heavier than had been expected. In 1908 the coal movement did not fairly begin until June.

New York

ANTHRACITE

June 16—The anthracite trade remains steady and without any special incident. May shipments showed a falling off from previous months in the year, but that was generally expected.

There is no change in prices. We quote for prepared sizes, \$4.45 for lump, and \$4.70 for egg, stove and chestnut, all f.o.b. New York harbor. For steam sizes current quotations are unchanged at \$3.10@3.25 for pea, \$2.35@2.50 for buckwheat, \$1.70@2 for rice or buckwheat No. 2, and \$1.25@1.50 for barley, f.o.b. New York harbor points.

BITUMINOUS

Consumers are evidently beginning to take more interest in the market, although they stir themselves rather more slowly than dealers would like to see. It is not to be denied that commercial trade is better, though it can hardly be called brisk as yet. All-rail trade continues the best. New York harbor prices are unchanged, lower grades selling at \$2.40@2.50, f.o.b. harbor shipping port, and better grades for \$2.60 and upward. Transportation is rather slow, but car supply is good.

In the Coastwise trade vessels are in good supply and freights continue low. For large vessels from Philadelphia rates are 75@80c to Lynn and Newburyport; 75@80c to Boston, Saco and Portland;

45@50c. to Providence and the Sound. From New York rates are 60@65c. to points around Cape Cod.

A subject of considerable interest and discussion in the trade is the present coal situation in England. The latest advices are that settlements appear impossible in Wales and in the Scotch districts, and it is very probable that there will be an extensive strike. In case this occurs a considerable business will be done here in export coal; not so much to England directly as to South America and other countries which are now supplied by English coal. Dealers here are looking out for this contingency.

Birmingham

June 14—An improved condition is reported in the coal market. The mines in Alabama are beginning to receive orders that warrant more activity in the operation.

State Mine Inspector Edward Flynn announces that 56 men have lost their lives by accident in coal mines in this State so far this year.

Considerable attention was attracted to the annual convention of District No. 20, United Mine Workers of America, this week in Birmingham. The organization is practically dead; the attendance at the convention not being large enough to warrant the renting of a hall, the meeting was held in the offices of the organization.

Chicago

June 14—Conditions in the coal market are somewhat better for the seller, owing to restricted shipments of the chief supply, Illinois and Indiana fine coals. The ordinary consumer is buying closely, evidently in the expectation that inactivity will force prices down to their lowest point for the year soon. Lump coal is especially inactive, and in some cases brings 15 or 20c. less than standard prices through demurrage sales. Domestic trade is practically at a standstill in bituminous and very sluggish in anthracite.

Illinois and Indiana coals bring, in car lots, \$1.75@2.25 for lump, \$1.65@1.75 for run-of-mine and \$1.40@1.70 for screenings.

Eastern coals share the general condition, the market being light but shipments lessened so that prices are fairly firm. Hocking, which has been in too large supply for several weeks, is somewhat improved as regards the amount on the

market, but receipts are irregular, and occasionally a consignment is sold at 10 or 20c. below the \$3@3.15 otherwise obtained. Youghiogheny is in light but steady movement at \$3.15 for 3/4-in. gas, and Pittsburgh No. 8 in 3/4-in. brings \$2.65.

Anthracite sales are particularly light owing to the June advance of 10c., which is expected to defer most of the buying for the month to its latter end.

Cleveland

June 15—Lake trade is still rather slow, and the demand in the Northwest is not yet such as to indicate a pressing call for coal. Only contract boats are in commission.

Local trade is improving slowly, and there are indications of good demand for steam coal. Prices show little change. Slack is in best demand. Middle district coal brings \$1.90@2 for lump; \$1.65@1.75 for run-of-mine; \$1.25@1.35 for slack. No. 8 district brings about 5c. more, except for slack, which is \$1.40 firm.

Pittsburg

June 15—Between 8,000,000 and 9,000,000 bu. coal have been shipped down the river in the past week, pretty well cleaning out the accumulation in the pools and harbor. There are plenty of empties at the tipples and the railroad mines will continue in steady operation for some time. The market remains rather quiet. Nominal prices are \$1.10 to manufacturers and \$1.20 to retail dealers, for mine-run at mines, these prices being shaded 5 to 10c. Slack is quoted at 60@65c. per ton.

Connellsville Coke—The appraisement of properties expected to be taken into the coke merger continues. The latest information is that while a merger will likely be put through, it will hardly comprise as large a portion of the independent coal acreage and coking capacity as the promoters have lately claimed. A number of important independents in the Connellsville and lower Connellsville fields are known positively as refusing to go in, while the merger will probably involve a larger acreage in Greene county, West Virginia and other fields than has been admitted. Some Connellsville interests, it is alleged, have put in their Connellsville holdings at moderate prices but have asked considerably above market values for outside holdings, and stipulate that all or none must be taken.

Prices remain at \$1.50@1.60 for prompt Connellsville furnace coke, contract coke being \$1.60@1.75; Connellsville foundry coke remains at \$1.80@2 for prompt and \$1.90@2.25 for contract.

The *Courier* reports the production in the Connellsville regions, week ended June 5, at 291,686 tons, an increase of 7000 tons, shipments at 3667 cars to Pittsburg district, 5734 cars to points west and 783 cars to points east of Connellsville; a total of 10,184 cars, a gain of 200 cars.

Foreign Coal Trade

United States Coal Exports—Exports of coal from the United States—heretofore reported—to which is now added coal supplied to steamships in foreign trade, four months ended April 30, long tons:

	1908.	1909.	Changes.
Exports.....	3,053,204	2,772,946	D. 281,158
Bunker coal.....	1,985,706	1,907,307	D. 78,399
Total.....	5,038,910	4,679,353	D. 359,557

Total decrease in coal sold for consumption beyond the limits of the United States this year was 7.1 per cent.

Austrian Coal Production—Coal production of Austria-Hungary, four months ended April 30, metric tons:

	1908.	1909.	Changes.
Coal	4,797,563	4,652,297	D. 145,266
Brown coal.....	9,325,169	8,497,733	D. 827,436
Total mined.....	14,122,732	13,150,030	D. 972,702
Coke made.....	627,188	600,666	D. 26,522
Briquets made.....	48,569	60,506	I. 11,937

The greater part of the briquets is made from brown coal, or lignite.

Spanish Iron Shipments—Imports of coal into Spain, two months ended Feb. 28 were 334,115 metric tons, an increase of 42,138 tons. Imports of coke 40,199 tons, an increase of 2400 tons.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on June 5: Best Welsh steam, \$4.02; seconds, \$3.84; thirds, \$3.60; dry coals, \$3.84; best Monmouthshire, \$3.48; seconds, \$3.30; best small steam, \$2.64; seconds, \$2.46. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, June 16—The iron and steel markets continue generally strong and active. A tendency to advance prices has been apparent in some lines, but no positive action in that direction has been taken.

In pig iron business has been more active and many inquiries have been received in addition to the sales made. Foundry iron is in fair demand, but the greatest activity has been in basic pig. The size of the lots sold shows some increase and orders are being placed farther ahead. Prices are firm as a rule, no general advance being made, but sellers are not making concessions, especially on future deliveries. The increased capacity of the furnaces in blast is a prominent feature in the situation, but does not seem to affect the market at all unfavorably.

In finished material building and bridge work continue to make an active demand for structural material. Sales of wire and wire products are rather smaller, but this appears to result from the fact that jobbers and dealers generally are well supplied, rather than from any diminution in demand. The same thing is the case with bars, but it is noted that store and jobbing trade is generally improving. In rails quite a number of small orders have been

placed for standard sections, but no large contracts are reported. Trolley rails and light rails show a considerable business.

Pig Iron Production—The statistics of the blast furnaces, as collected by the *Iron Age* show that on June 1 there were 233 coke and anthracite furnaces in blast, having an aggregate weekly capacity of 442,500 tons. This is 30,500 tons more than on May 1, and is the highest capacity reported since Nov. 1, 1907. The recent increase in furnaces in blast has been entirely in the steel-works furnaces; the merchant furnaces show no increase since December last. Making allowance for the charcoal furnaces, the estimated make of pig iron in May was 1,897,000 tons; for the five months ended May 31, it was 9,079,000 tons.

Lake Superior Iron Ore—Shipments of iron ore from the Lake Superior region for the season to June 1 are reported by the *Cleveland Iron Trade Review* as below, in long tons:

Port.	1908.	1909.	Changes.
Escanaba.....	10,245	384,856	I. 368,611
Marquette.....		133,097	I. 133,097
Ashland.....	21,128	210,855	I. 219,727
Superior.....	132,248	608,515	I. 475,997
Duluth.....	86,691	1,215,925	I. 1,129,234
Two Harbors.....	28,433	725,820	I. 697,387
Total.....	285,315	3,309,068	I. 3,023,753

Last year no considerable shipments were made before June. As compared with 1907, the shipments this year show a decrease of 2,943,193 tons.

Baltimore

June 14—Exports for the week included 1,317,352 lb. scrap tin to Rotterdam. Imports included 1309 tons ferromanganese and 9 casks silico-spiegel from Liverpool; 5400 tons iron ore from Cuba.

Birmingham

June 14—General conditions in the Southern territory have changed for the better. There is a better demand for pig iron, prices have begun to strengthen and plants are beginning to resume operations. No. 2 foundry iron is being quoted at \$11.50 per ton, minimum, for delivery during June and July, with \$12 for third-quarter delivery. Some iron has been sold already in this section above \$12 per ton, delivery during the fourth quarter. Inquiries are being received.

Four of the open-hearth furnaces at the steel plant at Ensley were started up during the past week. An order for 12,000 tons of rails has been received. Announcement is made that the reorganized company taking over the properties of the Southern Steel Company—of which W. H. Hasting, of Birmingham, is president—has \$1,500,000 necessary for working capital underwritten and the work of preparing the plants for operation will be begun.

Chicago

June 14—The iron market remains but slightly better than a week ago as regards

sales of pig iron, although inquiries are more numerous, sales of finished materials increasing and confidence more and more apparent. Consumers, to a large extent, are supplied for the third quarter; for the fourth quarter they are buying both Northern and Southern pig iron in lots from a carload up to 500 tons. Large requirements are being figured on in malleable iron. Prices remain firm at \$11.50 @12 Birmingham (\$15.85@16.35 Chicago) for Southern and \$16.50@17 for Northern, for third and fourth quarters. Some sales are made at 25 or 50c. above or below these prices, but not many. The selling interests are apparently firm.

In structural material the market continues active and railroad supplies also are in good demand. Coke is fairly active at \$4.70 (\$2.05 at ovens) and with the supply large.

Cleveland

June 15—Some sales of iron ore are reported still, but transactions have not been heavy, so far as can be ascertained. Arrivals for May at Lake ports were much larger than last year.

The breaking down of the lock gates in the Canadian canal at the Sault Ste. Marie on June 8, by a steamer running into the gates, will put the Canadian canal out of commission for some time. It does not, of course, affect the American canal, which will be able to pass all the vessels coming, but will be crowded with traffic as the season goes on. In busy times the Canadian canal carries about 20 per cent. of the traffic.

Pig Iron—No large transactions are noted, but many small sales, 500-ton lots and under. Sellers are firmer in their views, and are holding on a basis of \$15.25@15.50 for No. 2 foundry, Cleveland.

Finished Material—A good business has been done in bars and structural steel with a fair lot of plates. Structural shapes are quoted at 1.30@1.35c.; steel bars, 1.20@1.25c., Pittsburgh basis.

Philadelphia

June 16—The pig-iron market is somewhat quieter but a good deal of business is being done and prices are firm, with many furnaces holding for a little higher range on fourth quarter. A good tonnage of basic has been sold and pipe foundries are taking much iron, principally low-grade Southern. No. 2X foundry may be quoted \$16.50 for prompt and \$16.75 for third quarter. Basic is about \$15.50 per ton in this territory.

Steel Billets—Sales are fair with a good deal of inquiry. Prices are unchanged.

Bars—Business continues fair, demand being mostly for refined iron which sells in this territory at around 1.40c while 1.35c. is asked for steel bars. Store trade is good.

Plates—Sales of boiler and ship plates are reported good.

Structural Material—No large contract is reported this week but a good total of small sales. There is talk of increased prices, but it has not materialized so far.

Scrap—Demand and prices are going up. Dealers are sitting on their piles, afraid to let it go in view of the higher quotations promised. The biggest call is for heavy steel melting scrap, for which \$15.50@16 has been realized. Good casting is also in demand.

Pittsburg

June 15—While general buying of iron and steel products is not as heavy as during the recent rush, it is still of fair volume and the buying is amply sufficient to maintain the bullish feeling which has pervaded the trade. Bars, plates, shapes and wire products have been advanced slightly in the past few weeks. Shapes are fairly well held at 1.30c., Pittsburg, and plates at 1.25c., although occasionally these prices are shaded \$1 a ton.

In the past few weeks the railroads have been better buyers, but they are still far short of the average of 1906 and 1907. Other consumers are taking as large tonnages as ever, and the only question is as to the permanence of the movement. It is known that a portion of the material now being shipped from mills is going into stocks, but it is believed that the rate of consumption will increase.

Pig Iron—Prices in the local market have advanced again, by fully 25c. The Standard Sanitary Manufacturing Company late last week bought 5000 tons, for third-quarter delivery, divided among No. 2 foundry at \$14.50, Valley, No. 3 foundry at \$14, Valley, and gray forge at \$13.75, Valley. These prices could not be duplicated now. Gray forge has since sold at \$14.15, Valley, while No. 2 foundry is held at a minimum of \$14.75, Valley. Early last week sales of standard basic were made at \$14.25, Valley, but a couple of days later \$14.50 was paid for basic somewhat off in analysis, and the minimum of the market is \$14.75, which price has been done on third quarter, with \$15 and higher asked for fourth quarter. The Republic Iron and Steel Company has just bought 5000 tons of standard bessemer, following its recent operations by which it bought 10,000 tons and borrowed some 20,000 tons. Standard bessemer is at a minimum of \$15.25, Valley, most sellers asking \$15.50.

Steel—The market on sheet-bars is firmer since the sales in the past few weeks at cut prices, and \$25@25.50, delivered in the district, appears to be the best that can be done, while some mills are quoting \$26 on prompt delivery. Bessemer billets are firm at \$23, Pittsburg, while open hearth billets are scarce and premium of \$1 per ton is being asked.

Sheets—Demand has improved slightly and mill operations have increased, the leading interest operating about 70 per cent. of its capacity, while the independents are doing 75 per cent., or better. The Amalgamated Association is holding a "delegate convention" in Pittsburg this week anent the declaration of the American Sheet and Tin Plate Company that after June 30 it will operate all its mills on the open-shop plan. The men will probably try to close the hitherto union plants of the leading interest. This would have little effect in the sheet branch, but would be a serious matter in tinsplate. The sheet market remains at 2.20c. for black and 3.2c. for galvanized, 28-gage, these prices being occasionally shaded \$1 per ton. The open quotations on corrugated roofing are \$1.55 for painted and \$2.80 for galvanized, 28-gage, per square, but these prices are being shaded \$1 or \$2 per ton.

Ferromanganese—The market continues quiet. The regular quotation is \$40.50@41, Baltimore, equal to \$42.45@42.95, Pittsburg, but the lower price might be shaded 50 cents.

Foreign Iron

German Iron Trade—Exports and imports of iron and steel in Germany, four months ended April 30, metric tons:

	Exports.	Imports.	Excess.
Iron and steel.....	1,225,903	128,038	Exp.1,097,864
Machinery.....	97,309	19,765	Exp. 77,544
Total.....	1,322,211	147,803	Exp.1,174,708
Total, 1908.....	1,275,657	212,342	Exp.1,063,316

Imports of iron ore in this year, 2,364,201 tons; exports, 898,442 tons. Imports of manganese ore, 100,820; exp'orts, 794 tons.

British Iron Ore Imports—Imports of iron ore into Great Britain, four months ended April 30, were 1,890,279 long tons in 1908, and 1,850,677 in 1909; decrease, 39,602 tons. Of the imports this year 1,416,557 tons were from Spain.

Metal Markets

New York, June 16—The metal markets continue generally strong, but hardly as active as recently. A good demand for consumption is generally apparent.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

	Exports.	Imports.	Excess.
Gold:			
May 1909.....	\$11,171,265	\$ 2,263,729	Exp. \$ 8,907,544
" 1908.....	26,555,913	3,101,002	Exp. 23,454,911
Year 1909.....	55,487,891	17,767,857	Exp. 37,720,034
" 1908.....	44,891,257	22,958,223	Exp. 21,933,034
Silver:			
May 1909.....	4,428,448	3,867,388	Exp. 571,060
" 1908.....	4,928,334	3,394,608	Exp. 1,533,726
Year 1909.....	28,854,629	18,542,453	" 5,322,176
" 1908.....	21,077,165	17,688,150	" 3,389,035

Exports from the port of New York, week ended June 12: Gold, \$292,550, chiefly to Buenos Aires; silver, \$929,628, to London and Paris. Imports: Gold, \$101,631, chiefly from South America and Australia; silver, \$152,076, from the West Indies and Mexico.

Gold and silver movement in France, four months ended April 30:

	Imports.	Exports.	Excess.
Gold...	Fr. 208,958,000	F. 24,462,000	Imp. Fr. 179,496,000
1908...	230,164,000	2,318,000	Imp. Fr. 229,846,000
Silver...	42,931,000	41,735,000	Imp. Fr. 1,196,000
1908...	45,662,000	54,362,000	Exp. 8,700,000

Imports of copper and nickel coins, 27,000 fr. in 1908, and 26,000 fr. in 1909; exports 305,000 fr. in 1908, and 161,000 fr. this year.

Gold—The price on the open market in London continues unchanged at 77s. 9d. per oz. for bars. There was no special demand, and most of the gold offered was taken by the Bank of England. In New York there were no shipments direct to Europe, but \$2,250,000 were taken for export to Japan on London account.

Platinum—Business is rather quiet, but it is usually in that condition through the summer. Prices are unchanged, dealers quoting \$22.50@23 per oz. for refined platinum, \$25 for hard metal and \$18@20 for good scrap.

Silver—The market has been almost stationary through the week, fluctuations being very narrow.

SILVER AND STERLING EXCHANGE

	June.	10	11	12	14	15	16
New York...	52½	52½	52½	52½	52½	52½	52½
London...	24½	24½	24½	24½	24½	24	24½
Sterling Ex.	4.8775	4.8760	4.8775	4.8760	4.8775	4.8785	

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Exports of silver from London to the East, as reported by Messrs. Pixley & Abell, year to June 3:

	1908.	1909.	Change.
India.....	£ 3,684,018	£2,216,200	D. £1,367,818
China.....	516,400	1,076,100	I. 559,700
Straits.....	90,200	82,800	D. 7,400
Total.....	£ 4,190,618	£3,374,100	D. £ 816,518

Receipts for the week, £2500 from Australia, £5800 from the West Indies and £170,400 from New York; total, £178,700. Exports, £1800 to Egypt and £55,000 to India; £56,800 in all.

Copper, Tin, Lead and Zinc

	Copper.		Tin.	Lead.	Zinc.
June.	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.
10	13½	13½	60½	30	4.35
11	13½	13½	60½	29½	4.35
12	13½	13½	60½	29½	4.35
13	13½	13½	60½	29½	4.35
14	13½	13½	60½	29½	4.35
15	13½	13½	60½	29½	4.35
16	13½	13½	60½	29½	4.35

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—The persistent decline in the London standard market has discouraged buying on the part of consumers, both here and abroad. Sellers have been trying to make a market by offering concessions from day to day, but so far they have met with but little success. The actual business transacted has been of a negligible quantity, the market for Lake in particular being quite nominal. The close is weak at 13½@13¾c. for Lake copper; 13½@13¾c. for electrolytic copper in ingots, cakes and wirebars. The average of the week for casting copper has been 13@13¼c.

Copper sheets are 17c. base for large lots. Full extras are charged, and higher prices for smaller quantities. Copper wire is 15c. base, carload lots at mill.

The liquidation of long holdings and short selling, which did not meet with a proportionate inquiry by new buyers, brought about a rapid and uninterrupted decline in the standard market in London. The statistics published for the half month show an increase in the visible supply of 5400 tons. This news is adequate explanation for the weak closing quotations which are cabled at £59 for spot and £59 17s. 6d. for three months.

For refined and manufactured sorts we quote: English tough, £63; best selected, £62@63; strong sheets, £74@76.

The report of the Copper Producers' Association gives the following figures for May and the five months ended May 31, in pounds:

	May.	Five Months.
Stocks, May 1 and Jan. 1	183,198,073	122,357,266
Production in U. S.	118,356,146	564,825,116
Total supplies	301,554,219	687,182,382
Deliveries, dom. and exp.	131,706,078	517,334,241
Stocks, June 1	169,848,141	169,848,141

Production includes copper refined from all sources. Estimated exports for May, 70,387,520 lb.; for five months, 269,613,120 lb.; leaving for domestic deliveries, 61,318,528 and 247,721,121 lb. respectively. Decrease in stocks in May, 13,349,932 lb.; increase in five months, 47,490,875 pounds.

Owing to an error in transcribing, the May average for Lake copper was printed in our last issue at 13.228c. It should have been 13.238c., as given in the table this week.

Exports of copper from New York and Philadelphia for the week were 9068 long tons. Our special correspondent gives the exports from Baltimore at 1824 tons copper.

Stocks of copper in England and France on June 1 are estimated by Henry R. Merton & Co., at 56,854 tons; this including 5850 tons afloat from Chile and Australia. The total is an increase of 5936 tons over the May 1 report.

Tin—The activity in the London market which we reported last week has somewhat subsided. Notwithstanding the reduced transactions, the tone of the market remains steady and the close is cabled at £133 17s. 6d. for spot, and £135 7s. 6d. for three months.

The firmer London market has not had any influence on domestic consumptive buying. Traders also are reluctant in following the advance in London, and business in tin is practically at a standstill. Quotations at the close are 29¼ cents.

Supplies of tin in May, as reported by A. Strauss & Co., were 7734 long tons; deliveries, 6840 tons. The visible stocks June 1 were 19,818 tons, an increase of 894 tons during May.

Exports of tin from the Straits, three months ended March 31 were: United States, 5166; Great Britain, 6722; European Continent, 1360; China and India, 557; total, 13,805 long tons, a decrease of 2235 tons from last year.

Lead—There is a steady business doing in this metal at 4.35c., New York, and 4.27½@4.32½c., St. Louis. Chemical lead has sold at St. Louis at 4.35 cents.

The London market is somewhat lower, and the close is cabled at £13 1s. 3d. for Spanish and £13 3s. 9d. for English.

Spelter—The improvement in this metal has made further progress. Large orders are being placed daily, particularly by the galvanizers. The smelters are reluctant to engage themselves very far ahead, for in addition to the proposed tariff and the advancing ore market in Joplin, they have now to contend with labor difficulties. It is reported that a number of plants in Kansas are on dead fire because they have a strike on their hands on account of refusing the demand of their men for a raise in wages. The smelters are assuredly in a bad way. They are face to face with a scarcity of ores and the price of spelter does not leave sufficient margin as against the current price of ore. The import lists show constant importations of foreign spelter on an increasing scale, which it is understood is being used for drawback purposes. The close is firm at 5.25@5.30c., St. Louis, and 5.40@5.55c., New York.

New York quotations for spelter June 10 were 5.37½@5.40c.; June 11, 5.37½@5.42½c.; June 12 to June 13, inclusive, 5.40@5.45 cents.

The London market is somewhat lower, the close being cabled at £22 for good ordinaries, £22 5s for specials.

Base price of sheet zinc has been advanced $\frac{1}{4}$ c. to 7c. per lb., f.o.b. La Salle-Peru, less 8 per cent. discount.

Other Metals

Antimony—Sales are only of a retail kind. Prices are nominally unchanged at 83½c. for Cookson's; 7½c. for U. S.; 7¾@7½c. for other brands. Business is waiting a decision on the tariff.

Aluminum—No change is reported. No. 1 ingots are 22@24c.; wire, 31@32c. base; sheets, 33@34c. base.

Quicksilver—Business is fair only. New York price is unchanged at \$44.50 per flask of 75 lb. San Francisco, \$44 for domestic and \$42 for export. London, £8 7s. 6d. per flask, with 5s. less done by jobbers.

Nickel—Large lots, contract business, 40@50c. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotations 75c. per lb., in 100-lb. lots, at Cleveland, Ohio. In Germany, 450@475 marks per 100 kg. at factory.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Spanish Metal Exports

Exports of metals and minerals from Spain, two months ended Feb. 28, reported by *Revista Minera*, in metric tons:

Metals.	1908.	1909.	Changes.
Pig and manuf. iron	1,772	4,326	I. 2,554
Copper	1,421	1,929	I. 1,508
Copper precipitates	3,474	2,761	D. 713
Lead	26,304	22,052	D. 4,252
Zinc	402	54	D. 348
Quicksilver	422	211	D. 211
Minerals.			
Iron ore	1,062,628	1,075,208	I. 12,580
Manganese ore	1,874	1,929	I. 1,508
Copper ore	192,474	172,339	D. 20,135
Lead ore	686	370	D. 316
Zinc ore	13,283	18,325	I. 5,042
Pyrites	231,343	162,330	D. 69,013
Salt	92,264	89,219	D. 3,045

Imports of phosphate rock were 20,916 tons in 1908, and 15,832 in 1909; decrease, 5084 tons.

Zinc and Lead Ore Markets

Joplin, Mo., June 12—A number of the heavier producers declined to sell zinc ore this week under a base price of \$45 per ton of 60 per cent. zinc, and in order to fill shipping orders this price had to be met by purchasing agents. This is in excess of a ratio of \$8.50 per ton of 60 per cent. zinc for each \$1 per 100 lb. for spelter, which will need to reach \$5.65 per 100 lb. before it will be equivalent to a ratio of 8 to 1, the limit at which smelters claim there is a living profit in manufacturing spelter. Outputting conditions are good, and the reported discovery of 22 ft. of ore under the blanket

vein in one of the mines north of Webb City, said to carry a higher percentage of concentrate than the blanket vein, offers new possibilities for this ore area. The highest price paid was \$47 per ton, on a base of \$42@45. Heavy silicate shipments, selling at \$17@24 per ton, lowered the average to \$38.96. Lead ore sold as high as \$40 for several hundred tons for next week's delivery, \$59.50 being the highest settling price reported for this week. The average price, all grades, was \$58.42, bidding them stronger on medium-grade purchases.

SHIPMENTS, WEEK ENDED JUNE 12.

Year	\$36.63		\$34.31		\$53.93	

NOTE—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Platteville, Wis., June 12—The highest price paid this week for zinc ore was \$43; the base price of 60 per cent. zinc was \$42@43 per ton. Offerings of \$57@58 per ton were made for 80 per cent. lead ore; no sales or shipments are reported. The week's shipment was light, owing to three days' steady rain.

SHIPMENTS, WEEK ENDED JUNE 12.

Camps.	Zinc ore, lb.	Lead sulphate, lb.	ore, lb.
Platteville	624,690		245,000
Strawbridge	385,000		
Benton	304,550		
Hazel Green	275,350		
Galena	240,000		
Livinston	80,000		
Harker	64,850		
Linden	58,170		
Total	1,931,500		245,000
Year to June 12	62,212,430	2,316,480	4,391,490

In addition to the above there was

shipped to the American Zinc Ore Separating Company 431,200 lb., and to the Joplin Separator Works 136,400 lb. zinc ore.

Petroleum

June 16—Exports of mineral oils from the United States, five months ended May 31, in gallons:

	1908.	1909.
Crude petroleum	38,948,138	56,734,752
Naphtha	13,823,090	27,655,244
Illuminating oils	443,646,161	410,978,912
Lubricating oils	64,294,792	58,675,765
Residuum	25,783,031	40,909,758
Total	686,495,257	694,854,431

Paraffin is included in lubricating oils. The total increase this year was 8,359,174 gal., or 1.4 per cent.

Chemicals

New York, June 16—Deliveries on contracts continue steady and a little more spot business is noted in several lines.

Copper Sulphate—A fair amount of business is being transacted at unchanged prices, \$4.25 per 100 lb. for carload lots and \$4.50 per 100 lb. for smaller orders.

Nitrate of Soda—Prices are 2.15c. per lb. for spot material and 2.12½c. for futures. A fairly good business is being done at these quotations.

Arsenic—Sales for the week have been light, aggregating only about 75 tons. The market is rather weak, closing at 2¼@3c. for white arsenic.

Mining Stocks

New York, June 16—The general stock markets show little change from last week's report. There have been numerous fluctuations in prices in both directions, but no settled tendency in the market. There has been in some special stocks a good deal of liquidation, but others have held well. Prominent in the latter class are the Steel Corporation stocks which remain very strong. Today there was a considerable reaction, with many drops in prices; but at the close there was some recovery.

On the Curb there was moderately active trading only, and the movement of prices was divided, some stocks showing higher prices and others lower. Miami Copper, which has been quiet for some time, was rather prominent in the trading. The Cobalt stocks are looking up and there is a good deal of trading. Nevada stocks are inclined to be quiet.

It is reported that a controlling interest in stock of the old Quicksilver Mining Company, of California, has been sold to London parties.

Boston June 15—There has been little in price movements the past week to incite public interest in the local mining-share market. North Butte has been

active at times and made a high at \$63.7½ with subsequent reaction to below \$59, ex-dividend of \$1. It is generally believed that control of this company is lodged in hands close to Amalgamated Copper interests. The violent fluctuations in the stock the past month or two have resulted in a change of ownership, according to best authorities.

Mass mining has been less conspicuous with an extreme fluctuation of \$2, or from \$11 to \$9. By official utterance the company admits that the recent mill run was but 18 lb. of mineral to the ton of rock treated. The market end of the stock was almost a battle royal between the bull and bear parties, but the latter won out.

American Zinc and Franklin mining have been active in the limelight. The former stiffened \$1.25 to \$27.12½ largely on pool orders. About all the stock offered has been taken. Franklin advanced \$2.25 to \$18.50, but did not hold all of the advance. Copper Range had a smart spurt of \$2 to \$84.50, but a reaction which set in today took the price back to below \$82.

Amalgamated is off \$1.75 net for the week to \$84.62½, but the decline occurred almost entirely today, and the weakness of the New York market was responsible for it. To a greater or less extent the whole mining-share list weakened.

Price changes on the Curb are slight in net results for the week. Activity continues in the better grade of stocks, which is the encouraging feature.

Industrials

A book on blast hole drilling with well drills is being compiled by the Keystone Driller Company, of Beaver Falls, Penn., to be published in connection with the 1909 edition of Catalog No. 4. The editor will be glad to receive from any source drilling records and general information on the subject to be embodied in the text. The book will be distributed freely among reputable engineers and contractors.

Particularly noteworthy of present activity is a contract placed with Allis-Chalmers Company by the Milwaukee Electric Railway and Light Company for two 1500-k.w. motor-generator sets, one 500-k.w. balancer, six 2000-k.w. transformers, two 300-k.w. transformers, two 300-k.w. motor generator sets and a 300-k.w. generator of the water-wheel type, much of this apparatus constituting a "repeat" order.

The Bulger Block Coal Company's mine, at Bulger Station, Penn., is located in what is known as the Pan Handle district, where the conditions with respect to the application of coal-mining machines are notoriously severe, because of the presence of sulphur bands and "nigger heads" at the bottom of the vein where the cutting is done. After a thorough trying-out process two pneumatic coal punchers have been installed for use in conjunction with electric chain machines.

The department of water supply of the city of New York has been supplied with three 1500-ft. portable drilling machines by the Keystone Driller Company, of Beaver Falls, Penn. The machines are to be used for putting down wells on Long Island for the water supply of the borough of Brooklyn. The rigs are the same as the regular No. 15 oil rig, except that the boiler, which is mounted on a separate truck and located at a distance for oil and gas drilling, is in this case mounted on the machine.

The city of Bellevue, Iowa, has placed an order for a Foss three-cylinder vertical engine with gas producer complete, with the Foss Gas Engine Company, Springfield, Ohio, to replace a steam engine in the city electric-light plant. This will run in parallel with a steam engine, it being anticipated that the remaining steam engine will be displaced by another like engine. This improvement will make a large saving in operating expenses. The Foss Company are doing a large business in these producer plants, both for electrical work and pumping installations, and anyone considering equipment in this line should communicate with them.

The Wood Drill Works has issued a booklet entitled "Glances of the Panama Canal," which is a non-technical review of the canal by Warren Wood, proprietor of the Wood Drill Works, and Robert J. Wood, manager of the Chicago offices. It is a 16-page booklet, 9x6, containing cuts of the Gatun Dam, Culebra cut, the old Santo Domingo church, and several cuts of the "Wood" rock drills at work on the Porto Bello quarry, the rock from which will be used in the construction of the Gatun Dam; also a picture entitled "Jumbo and the Brownie," showing the largest and smallest drills made by that concern, Jumbo having a capacity of 50 feet and Brownie four feet. Copies can be obtained at any of the company's sales offices.

Along with other industrial organizations which have reported substantial gains in business during the last two months, the Western Electric Company's April returns make a slightly better showing than March, which was considerably the best month in the fiscal year to that time, and April, 1909, is nearly 50 per cent ahead of the returns for April, 1908. In view of the company's steady expansion during the last ten years and the high record for the peak year of 1906 when sales ran up to \$69,245,561, an increase of more than \$25,000,000 over the preceding year it is difficult to determine the making comparisons, what should be taken as the normal year, and at the present time

the Western Electric is operating at the annual rate of 65 per cent. of the record of 1906 and about 85 per cent. of the record of 1907, which was the second best year in the company's history, with sales totaling \$52,724,168.

The American Locomotive Company has recently issued pamphlet No. 10,035 of the above title, which illustrates and describes the joint exhibit of that company and the Atlantic Equipment Company at the exposition now in progress at Seattle, Washington. The exhibit consists of a rotary snow plow, built for the Chicago, Milwaukee & Puget Sound Railway; two locomotives, each representing the builder's new standard design of its type; one, a six-coupled tank or 2-6-2 T-type locomotive for logging service, and the other, a 10-in. by 16-in. four-wheel saddle tank contractors' locomotive; an electric motor and trailer truck, built for the Southern Pacific Company, and a new model, class 45-16-2-3, Atlantic steam shovel. A separate chapter is devoted to each equipment exhibited in which is illustrated the machine itself, and the special features of the design are briefly described. Reference is also given in each chapter to other of the company's publications presenting different designs and types of the same class of equipment, and on page 31 is an index of all the catalogs in print issued to date by the two companies.

The Macbeth Iron Company, of Cleveland, Ohio, and the Bruce-Meriam-Abbott Company, also of Cleveland, were consolidated on June 1, the name of the new company being the Bruce-Macbeth Engine Company. Both of the above companies have been long established in Cleveland, and their amalgamation makes one of the largest and strongest companies of its kind. The Macbeth Iron Company dates from the year 1870, having been known until late years as Macbeth and Company; the Meriam-Abbott Company, predecessor of the Bruce-Meriam-Abbott Company, was organized in 1900, and has been one of the pioneers in the manufacture of the commercial gas engine and its development to the present standard of perfection. It is the purpose of the Bruce-Macbeth Engine Company to continue the business of both of the former companies on a much larger scale than before. The manufacture and development of the gas engine will be continued and the former line of work of the Macbeth Iron Company, building of blowing engines and general machine and foundry work, will be conducted as heretofore.

The Cyccone Drill Company, of Orrville, Ohio, has made the following shipments of machines in the past few days: two complete core drilling outfits for E. C. Hargrave, to be used on his property near Port Arthur, Canada; blast hole drill to the Rio Tinto Company for its railroad construction in Spain; large prospecting machine to W. H. C. Downes, which will be used in western Australia; complete prospecting outfit for the Santa Rita Company in New Mexico, which is the third machine purchased in the past few months; two prospecting outfits to the Rockdale Iron Company, which will be used for prospecting iron ore in Tennessee; complete prospecting outfit for the Xapier Iron Company, which will also be used for prospecting iron ore in Tennessee; well drilling machine and equipment to G. A. Amsink & Co., Columbia, S. A.; also a great many local shipments covering the regular types of machines and a number of gasoline traction outfits. The company reports a splendid business during the spring and an increasing number of inquiries for various kinds of equipment. The factory is running full time and increasing its working force.

In a pamphlet entitled "Automatic Draft Control for Steam Boiler Furnaces," the Green Fuel Economizer Company, of Mattewan, N. Y., describe an improved appliance recently brought out by that concern for so regulating the draft of steam boilers that the pressure within the fire-box is at all times neutral. To accomplish this end just enough pressure is supplied under the grates to force the air through the fuel,

while enough draft is applied in the smoke flue to draw the gases of combustion through the boiler. This is said not only to give the ideal proportion of air for perfect combustion at all loads but also to prevent the escape of flame and hot gases of combustion through the open fire-door and through crevices in the brick-setting, as where forced draft is used, while also preventing the drawing in of cold air and the dilution and consequent cooling of the gases of combustion, as where induced draft only is used. This system of draft has an important bearing in connection with the researches which have recently been made by the engineers of the United States Geological Survey with the object of increasing greatly the rate of steam production per sq. ft. of heating surface in steam boilers.

A new booklet of 24 pages, entitled, "The Proper Care of Belts," recently gotten up by the Joseph Dixon Crucible Company, Jersey City, N. J., is divided into three sections, headed respectively: Belts, belt dressings, and hints, kinks, tables. The first section deals with the running condition of belts; the second takes up treatment with various preparations; and the third, as the title indicates, has some general points upon belting and its use. This last section contains a considerable amount of interesting and valuable matter collected from many authoritative sources. It tells what results were secured in a plant where records were kept over a period of years; gives the economical speeds at which leather belts should be run; has some matter telling of the different styles of joints, illustrating three methods of leather lacing; contains rules for calculating speed of pulleys; gives horsepower transmitted by various sizes of single and double belts, etc. Anyone who has any amount of belting under his care should have a copy of this booklet. While it is gotten out in the interests of the traction and solid belt dressings that the Dixon company places on the market, it contains so much matter of general interest as to be valuable to the practical man. Those desiring a copy of this booklet may secure same by writing direct to the home office of the Joseph Dixon Crucible Company, at Jersey City.

NO. 26.

Operations in the Cobalt District, Ontario

Ore Carrying from 1000 to 8000 Oz. Silver per Ton Mined from Narrow Veins; Product Shipped out for Smelting; Growth of the Camp

B Y E D W I N H I G G I N S

Cobalt lies in the northeastern part of Coleman township, in the Province of Ontario. It is distant about 330 miles northerly from Toronto, and may be reached by an overnight trip from that city over the Temiskaming & Northern Ontario Railway, a road built and operated by the Canadian government. Cobalt has a population of about 6000, and the town, or camp, stretches along the northwestern shore of Cobalt lake. The chief producing mines of the district lie within 2½ miles

with steep faces often rising to a height of 100 ft. or more.

GEOLOGY

There are in and around the Cobalt district a great variety of Pre-Cambrian rocks; also prominent outcrops of the Niagara of the Silurian. Between the Niagara and the Pleistocene there are no formations represented in the district. The oldest series of the district are the Keewatin and Laurentian. The Keewatin is

face, consists of conglomerates, gray-wack-slate and impure quartzites. These rocks contain fragments of the granite, greenstone and other representatives of the older series. This formation, the Lower Huronian, contains most of the cobalt-silver veins.

The veins cut through all these series, but the most productive are usually in the rocks which contain more or less coarse fragments. It is believed that the fissures now occupied by these veins were pro-

RIGHT-OF-WAY SHAFT NEAR RAILWAY TRUCKS, SILVER QUEEN IN BACKGROUND

of the town. The elevation of Cobalt lake is 968 ft. above sea level.

To those familiar with the mining districts in the western part of the United States, the Cobalt district presents a most striking contrast. Unlike many of the western mining camps where bleak hills and little or no water is the rule, the Cobalt district is well covered with vegetation and timber; the country for many miles around is plentifully supplied with water in the form of rivers, smaller streams and innumerable lakes. The surface presents an uneven appearance, hills

an igneous complex, consisting of greenstones, quartz porphyries and other rocks. It has been more or less folded and disturbed. The Keewatin is cut through by a medium- to coarse-grained granite to which the name Laurentian is applied. The Keewatin rocks, however, were folded before the intrusion of the Laurentian.

After the Laurentian intrusion, the surface was subjected to erosion for a long period and these rocks, together with the Keewatin, were worn down. The oldest fragmental material that lies directly on the eroded Keewatin and Laurentian sur-

duced at the time of the eruption of the younger, post-Middle Huronian diabases. The Lower Huronian probably has a thickness of at least 500 ft. in some cases. Being laid down on an uneven surface, its depth at different points is quite variable. The Middle Huronian is represented in the series of arkoses, together with conglomerates and quartzites, of the township of Lorraine.

The post-Middle Huronian diabase occupies a large part of the surface of the area. In most cases, where associated with the Huronian, these rocks seem to

occur in the form of sheets or sills, spreading between or over the layers of the rocks through which they cut. After the eruption of these diabases, whose exact age is not known, erosion of the surface again took place for a long period of time and all the series now exposed in the field, with the exception of the younger Niagara, were worn down. Much of the surface of the area is occupied by boulder clay and loose bedded deposits.

VEINS

Most of the cobalt-silver veins occur in the Lower Huronian. Several have been found in the diabase and in the Keewatin. Most of the Keewatin rocks are tougher and do not fracture with the same ease as the overlying series of the Lower Huronian; hence the solutions

approximately northeast and southwest, while that in the northwest corner of the Nipissing location, on the southeastern border of lake Cobalt, strikes northwest and southeast. The vein in the southwest corner of this location strikes east and west, which is the direction of strike of the majority of the veins. The veins vary in width from 1 to 14 in., the majority being not over 6 in. in width. In some cases there occurs what may be called a system of veins, three or four roughly parallel fissures sometimes making a mineralized width of about 20 to 30 in. The veins usually stand practically vertical. There are examples of veins that run from the Huronian conglomerate into the underlying Keewatin; there are veins *e. g.*, one on the Lawson property, that run horizontally from the Keewatin into the diabase; the

difficult to predicate the original source of the metals—silver, cobalt, nickel, arsenic and others. They may have come up from a considerable depth with the waters, or they may have been leached out of what are now the folded and disturbed greenstones and other rocks of the Keewatin.

DISCOVERY AND GROWTH OF THE CAMP

Cobalt's growth, since its discovery a few years ago, has been remarkable. The first discovery of mineral was made on Aug. 15, 1903, during the building of the Temiskaming & Northern Ontario railway, on what is now the McKinley-Darragh property; the second discovery was made Sept. 15 of the same year, on the La Rose property. These discoveries, however, aroused little interest, and it was not until October, when a sample of the mineral

LOOKING NORTH ON COBALT LAKE—RIGHT-OF-WAY MINE ON THE RIGHT

have not had the same freedom of movement in the former as in the latter. Insofar as the precipitation effects which the rocks of either series may have on solutions working through fissures in them, there seems to be little difference between the two. Many of the pebbles and boulders and much of the cement material in the Lower Huronian, have been derived from the underlying Keewatin. Hence one would think they would have about the same influence in precipitating substances from solution, as the rocks in the latter formation.

The more important veins so far found in the Lower Huronian lie in what may be called two parallel belts. Although these two belts have a strike approximately northeast and southwest, this direction is not maintained throughout. The veins on the Trethewey and Coniagas strike east and west. The main veins on the La Rose and McKinley Darragh strike

Nova Scotia vein runs downward from the Keewatin into the underlying diabase.

THE ORES

The more important ores in the veins are native silver (associated with which is usually some dyscrasite, argentite, pyrrargyrite and other compounds of the metal), smaltite, niccolite and related minerals. Many of the minerals are intermixed in the ores, and for this reason some of them have not been clearly identified. Calcite forms the chief gangue, but some of the veins contain only a small amount of this material. Quartz and fragments of wall rock are often found intermixed with the ores. The minerals making up the vein filling have, in all likelihood, been deposited from highly heated and impure water which circulated through the cracks and fissures of the crust and were probably associated with the post Middle Huronian diabase eruption. It is rather

was given to T. W. Gibson, director of the Bureau of Mines of Ontario, that outside attention was directed to the discovery. Mr. Gibson recognized the mineral as niccolite, and forwarded it to Willet G. Miller, provincial geologist. Mr. Miller immediately visited and examined the district, and published his first report in November, 1903. For some reason, probably the failure of previous mining booms in other districts, little enthusiasm was awakened until 18 months later, when the public began to learn of the rich shipments of ore being made from the Cobalt district. The real rush of prospectors and investors began about the middle of 1905. Since that time the progress made has been almost without parallel. In 1908 the mines had been developed to such an extent that Cobalt supplied nearly 9 per cent. of the world's production of silver. The principal shippers during 1908 were Nipissing, La Rose, Coniagas, O'Brien, Kerr

Lake, Trethewey, Silver Queen, Temiskaming & Hudson Bay, Townsite, Right of Way and Crown Reserve; in addition to these there were about 30 other properties from which varying tonnages of ore were shipped. Several shippers have been added to the list in the present year. The accompanying table, compiled from different reliable sources, will give an idea

Coniagas, 150; Buffalo, 200; Trethewey, 175; Temiskaming & Hudson Bay, 225; O'Brien, 300; Chambers-Ferland, 150; McKinley-Darragh, 250; Townsite, 100; City of Cobalt, 175; Right-of-Way, 180; Nancy Helen, 175; Nova Scotia, 350; Silver Queen, 175.

Owing to the fact that the silver ore is not confined entirely to the narrow

sacked for shipment; mixed pieces are also picked out, the lean portion cobbled, and the resulting high-grade ore sacked for shipment. All material passing over the table goes to the concentrator. This practice is varied in certain minor details at some of the mines.

CONCENTRATION

In the concentration of the ore the general practice is to crush to from 20- to 30-mesh, following this by classification and treatment on various tables and slimmers. The average concentration is about 40 into 1. The variations in arrangement depend on the nature of the ore to be treated. The Buffalo concentrator reduces its ores with crusher and rolls, sizes in trommels and sends the different sizes to five jigs. A Chilean mill is used instead of stamps. Sands are treated on four Deister tables, while the slimes go to Callow settlers; the

of the growth of the Cobalt district since 1904. Up to the second quarter of 1909, over \$10,000,000 had been paid in dividends by Cobalt silver mines. Among these, Nipissing, La Rose, Temiskaming & Hudson Bay, Crown Reserve and Kerr Lake furnished a large percentage of the total.

MINING

In the early days of the camp all of the ore was won by open-cut mining. At present the bulk of the ore is mined through vertical shafts with levels at various intervals; open-cut operations, however, are still to be found on a few of the properties.

Following are the approximate depths attained by some of the more important operations: Nipissing, 200 ft.; LaRose, 325; Crown Reserve, 200; Temiskaming, 300; Kerr Lake, 125; Cobalt Central, 400;

veins, but is found more or less disseminated in the wall rock on either side, no attempt is made to mine the vein matter separately. Everything is shot down to a stoping width and sent to the surface.

The practice of picking and cobbing is general in the camp. As carried on at several of the mines, the practice is as follows: The ore is dumped from the skip onto a coarse grizzly or screen, the material passing through being sent to the concentrator, although in some cases it is rich enough for shipment to the smelter. All overs from the grizzly pass slowly down a slightly inclined bumping table. Before starting on its course down the table the rock is washed by means of a spray of water, this process enabling the pickers, who stand on either side of the table, to more readily recognize the rich ore. High-grade ore is picked out and

overflow from the settlers goes to a cyanide plant, the remaining material being treated on three Deister slimmers.

At the Coniagas concentrator the rock is broken in crushers and rolls and fed to three trommels. The $\frac{3}{8}$ - and $\frac{1}{4}$ -in. sizes are jigged, the undersize going to a classifier. The overflow from the classifier goes to a settling tank, the material from which is treated on a Frue vanner. The sands from the classifier are treated on a Wilfley table. Thirty stamps are used here.

The Nipissing Reduction Company's concentrator crushes to $\frac{1}{2}$ in. and reduces the rock to 16-mesh through rolls. The material is then sized to 16-mesh, which goes to a Wilfley table; 40-mesh, which goes to a James table; 60-mesh, which also goes to a James table; and slimes, which are treated on a James slimmer.

The following seven concentrators are now in operation at Cobalt: Buffalo,

capacity 80 tons; Cobalt Central, 100 tons; Coniagas, 125 tons; King Edward, 40 tons; McKinley-Darragh, 80 tons; Northern Customs Concentrator, 80 tons; Nipissing Reduction Company, 80 tons. The capacity of the Northern Customs Concentrator will soon be increased to 120 tons. The New O'Brien concentrator will probably be completed before the end of July; its capacity will be 120 tons. The Colonial Mining Company is building a

idea of the probable production in 1909 may be gained from the statement of shipments during different periods up to the present time. The following shipments were made during the week ending on the dates stated: Feb. 27, 1,056,490 lb.; March 20, 1,182,360 lb.; April 17, 1,197,513 lb.; May 1, 1,013,196 lb.; May 29, 1,078,978 lb. Unless the production increases or decreases appreciably, the output for 1909 will probably be between 26,000 and 28,000

of the American Smelting and Refining Company. The high-grade ore, which carries as high as 8000 oz. silver per ton (average from 2000 to 2500 oz.) is treated principally at the Deloro Mining and Reduction Company's works, at Deloro, Ont., and at the Canadian Copper Company's smeltery at Copper Cliff, Ont. In addition to the plants mentioned above, ore is shipped to the following works: American Smelting and Refining Com-

LA ROSE SHAFT AND PART OF PUMP

concentrator; this is expected to be completed in August. The Temiskaming & Hudson Bay company will also erect a concentrator

OUTPUT AND VALUE OF THE ORE

As may be noted in the accompanying table, the production of the Cobalt mines was 25,362 short tons in 1908. This output is greater than the combined production of the four previous years. Some

tons, a slight increase over that of 1908. The chances are that the above estimate will prove too low. The average silver content of the ore shipped during 1908 was 725 oz. per ton. This compares with 677 oz. in 1907, and 1013 oz. in 1906.

SMELTING

Most of the low grade ore of the camp, which contains from 100 to 150 oz. silver per ton, goes to the Denver, Colo., plant

pany, Perth Amboy, N. J.; Balbach Smelting and Refining Company, Newark, N. J.; Pennsylvania Smelting Company, Carnegie, Penn.; United States Metal and Refining Company, Chrome, N. J.; Consolidated Mining and Smelting Company, Trail, B. C.; Coniagas Reduction Company, of Canada, Thorold, Ont.; Beer, Sondheimer Company, Hamburg, Germany; Anglo-French Nickel Company, Swansea, Wales.

Treatment charges vary from \$7 to as high as \$40 per ton, depending entirely on the grade of the ore and, in some cases, on the content of cobalt, arsenic and nickel. The Canadian Copper Company and the Deloro Mining and Reduction Company pay for over 6 per cent. cobalt in the ore, provided, however, that the nickel content is lower than the cobalt. The Anglo-French Nickel Company pays for cobalt on a sliding scale, the price ranging from 35c. for 8 per cent. to 55c. per lb. for 16 per cent. and over. Nickel is not paid for, its presence being considered detrimental. Although the arsenic in the ore is saved and marketed in the form of white arsenic by several

The cost of producing silver varies greatly. The average, however, may be said to be between 9 and 10c. per ounce.

The boiler plants of the Cobalt district represent a total of approximately 10,000 horsepower; there are over 60 compressors, with a maximum capacity of about 40,000 cu.ft. of free air per minute. The cost of power is, approximately, \$125 per horsepower-year. On the completion of the two power plants now building on the Montreal river, it is expected that the cost of power will be reduced to at least \$75 per horsepower-year. The plant at Hound Shoot will furnish electrical power, while that at Ragged Shoot will furnish compressed air. The compressed-

Carbon Dioxide in Producer Gas

Bulletin No. 30, on "The Rate of Formation of Carbon Dioxide in Gas Producers," by Dr. J. K. Clement, I. H. Adams and Dr. C. N. Haskins, has just been issued by the Engineering Experiment Station of the University of Illinois.

The problem attacked by the writers of this bulletin was the determination, so far as possible, of the factors that govern the production of carbon dioxide in gas producers. The chemical reaction expressed by the equation

which is fundamental in the action of the

CHAMBERS-FERLAND MINE ON LEFT; O'BRIEN MINE ON RIGHT

AT KERR LAKE—LAWSON SHAFT TO LEFT, CROWN RESERVE ON EDGE OF LAKE, KERR LAKE No. 7 TO RIGHT

smelters, few, if any of them, allow anything for the arsenic present in the ore.

LABOR, POWER AND COSTS

Labor at Cobalt is made up of Canadians, some Frenchmen from the lower province, Italians and a few Americans and Finns. There is no set wage scale. The union scale of wages is as follows: Drillers, \$3.50 per day; helpers, \$3; muckers, \$2.75; surface men, \$2.50; shaft work, 25c. advance. A small proportion of the miners are union men, and the wages in general may be said to be about 15 per cent. less than the above figures.

air plant will utilize the Taylor system, by which pressure is secured without moving machinery. This system is fully described in the JOURNAL of Jan. 19, 1907, page 125.

The geology of the Cobalt district has been fully and ably covered by Willet G. Miller, provincial geologist of Ontario, and appears in Vol. XVI, Part 2, of the report of the Bureau of Mines, 1907. I have quoted freely from Mr. Miller's report in the part of this article dealing with the geology of the district. The balance of the notes were gathered on a recent brief visit to Cobalt.

gas producer, was studied and a differential equation for the reaction-velocity derived. From this equation the velocity constants and the equilibrium constant were calculated from observed values of the percentage of CO formed in given time intervals. The rates of variation of these constants with the temperature were determined, and these were found to agree with van't Hoff's laws. From the constants thus determined it becomes possible to calculate the percentage of CO formed for any time of contact of carbon and CO₂ and at any temperature.

In the experiments performed, CO₂ gas

was passed through a porcelain tube filled with either charcoal, coal, or coke and heated in an electric furnace. The time of contact could be varied at will and by changing the current a temperature range from 700 deg. to 1300 deg. C., was obtained. Analyses were made by the Hempel method, both CO_2 and CO being absorbed.

It was found that the production of CO formed depends upon (1) the temperature, and (2) the time of contact of gas and carbon. With ordinary depth of fuel bed a high percentage of CO requires a high temperature—1300 deg. C. or above.

In an appendix, Dr. Charles N. Haskins has given a method solving the reaction-velocity equation and has established a criterion for the applicability of the general differential equation to the reaction under investigation. He has also shown that the same general method of solution may be applied to various other types of equations of reaction-velocity.

Slag Granulation and Explosions

By RICHARD HUTCHINSON

If a thin stream of molten furnace slag is poured into cold water the slag breaks into small pieces. This operation, termed granulation, is due to the small thermal conductivity of the slag. When the slags are not clean but contain small quantities of metal, speiss or matte they may cause an explosion when poured into water. It is well known that when molten lead is poured into wet molds an explosion will occur that scatters the hot lead in all directions; it is not, however, so well known that molten copper will float the water and not cause an explosion when treated in the same manner.

At first my opinion was that the phenomenon was due to latent heat; but since the latent heat of copper is 43 calories and that of lead 5.37 calories, it is evident that if this were the only cause the copper should create the greater explosion. The next assumption was that latent heat and thermal conductivity were both involved, but this theory was not entirely satisfactory, from the fact that if copper is allowed to fall 12 or 15 ft. and strike on a wet iron floor it too will explode, whereas it will not explode in a wet mold. I, therefore, settled on the theory that since all bodies cool from the interior outward, and only chill on the exterior when they have lost a quantity of heat, the phenomenon must be due to the thermal conductivity of the metals.

If the thermal conductivity of silver is 100, then copper is 71, iron 11.9, lead 7.9 and slag about 0.18. Owing to the diffusivity of copper being 3.6 times as much as lead, it is able to transmit its heat to surrounding objects without forming a crust that will confine the water between

it and the sides of the mold; at the same time the steam will bubble up through the molten copper. This is not the case with lead which chills almost immediately, forming a crust that confines the water and then converts it into steam which, expanding quickly, throws the lead out of the mold.

It is possible that the lead crust cracks and the water coming in contact with the molten interior generates the explosion as in the case of metal in slag when that is poured in water; in any case, however, the diffusivity of lead is so slow that the outer portion is chilled before the inner portion has lost its latent heat, thus reversing the natural condition of cooling from the interior outward. In the case of copper falling some distance, the metal has transmitted its heat to the surrounding atmosphere and has reached the stage where it has little heat to transmit and consequently chills, but still has sufficient latent heat remaining to cause an explosion.

Diffusivity, as defined by Hastings and Beach, is the velocity of the temperature change of a metal and is the ratio between

The Engineering & Mining Journal, N.Y.
RETORT-CHARGING APPARATUS

the conductivity of a metal and its specific heat. By calculation, the diffusivity of lead is 219 and that of copper 777, giving the 3.6 factor mentioned. The practical deductions are that metals with low-heat conductivity cannot be safely poured in wet molds, and that metals of high conductivity can only be poured in wet molds when the speed of pouring exceeds their diffusivity. Matte which has low conductivity cannot be poured into wet molds. The lack of literature on this subject was first called to my attention in 1903.

Apparatus for Charging Zinc Retorts

The difficulty of charging zinc retorts by hand and the excessive wear of drum casings in most of the mechanical devices are claimed to have been eliminated in the apparatus, described by Emile Dor-Delatre in his British Pat. 13,822 of 1908. The apparatus is to be carried by a traveling

crane and consists essentially of a rotary propeller or conveyer, rotating within a casing having a tangentially-disposed charging tube *F*. The propeller or conveyer consist of two disks, *P* and *Q*, connected by the blades *G*. The disk *P* is attached to the shaft of an electric motor, while the disk *Q* has a circular opening in the center, through which the ore from the hopper discharges. The feed is controlled by a valve, operated by the hand-wheel *M*. The disks *P* and *Q* are not parallel, but incline toward their periphery, so as to facilitate the entrance of the material and its immediate gravitation to the shallow blades *G*. In order to eliminate the effect of centrifugal force and obviate as much as possible the friction of the ore on the blades and walls of the casing, the blades are made short, and being away from the central intake the material does not become involved in the rotation of the wheel immediately on entering the apparatus, and is, therefore, not projected centrifugally against the walls of the casing, but falls by gravity to that part of the periphery of the conveyer which is passing the charging tube, and is at once projected into the latter by the propelling effect of the blades.

Tin in Australia

Alluvial tin has been discovered recently near Pine creek in the Northern territory. According to a description in the *Mining Journal*, May 8, 1909, furnished by the chief warden, E. C. Playford, this discovery is in a large granite area in the Pine creek slate and sandstone belt. The tin ore is found about 13 miles southwest of Pine creek, in the channel of one of the main branches of Spray creek. The granite area of this particular place forms a basin, bounded on the northwest and south by sandstone-capped tablelands, and partly inclosed to the east by table-topped hills from 150 to 200 ft. high. The branch of Spray creek referred to has formed a rough, deep, gorge with precipitous cliffs on each side, over 100 ft. high. Alluvial tin is found from near the entrance of this gorge to the head of the main branch.

At present 15 men are working on this alluvial deposit and are obtaining about 25 lb. of tin per day, each. This tin ore is black, with a little brown, ruby, amber and wood tin. In the lower regions of the main branch it is exceptionally fine, but higher up and in some of the smaller creeks is much coarser. Mr. Playford considers that this field will yield a large amount of alluvial tin, but is not favorably impressed with the possibility of finding payable tin-bearing veins. All the rock consists of a gray granite and sandstone, with a little quartz that can be classed as destitute of any valuable minerals. A small amount of monazite has also been found with the tin.

The Mineral Production of New York in 1908

By D. H. NEWLAND*

The year 1908, which will be remembered as an after-panic year, witnessed a marked reversal of conditions in the mineral industries of New York. Prosperity and steady expansion, that had so long prevailed in these industries, was succeeded by general depression and contraction, which continued with little or no relief throughout the 12 months. There were few mines or quarries that did not curtail operations, and many of them were closed down for at least a part of the year. The decline in productive activity was out of proportion to the rate of growth in the preceding years, so that the outputs of most materials were well below the totals recorded for 1907. Though the setback will doubtless prove only a temporary feature, it is certain that some time must elapse before the former activity is fully restored.

The statistics of mineral production in New York for the past year have been compiled by the State geologist's office in coöperation with the U. S. Geological Survey. The accompanying table (1), reported by the New York State Museum, gives the production of the more important minerals in New York for a period of years; table 2 gives the 1908 production of sundry minerals in the State. Though the 1908 figures for clay products, stone, sand and natural gas, which are totals from a large number of producers, are subject to further revision, they are believed to be substantially correct as they stand.

The total value of the output reported for 1908, based upon the materials in their crude or first marketable forms, was \$29,517,942. Compared with the total of \$37,140,606 recorded in 1907, this showed a decrease of \$7,622,664, or about 20 per cent. The output in 1907 was the largest ever made in the State, though it did not greatly exceed that of 1906, which was valued at \$37,132,832. The corresponding total for 1905 was \$35,470,897 and for 1904, \$28,812,595, or a little less than the total for last year.

EFFECT OF THE FINANCIAL DEPRESSION

Among the different departments of the mineral industry, iron mining was one that experienced the full measure of the depression, as it also had been among the first to respond to the prosperous conditions of the preceding years. The output amounted to 703,473 long tons, against 1,018,013 tons in 1907. The production was made by 10 mining companies, as compared with 13 reported active in 1907. The loss was shared

by all the districts, though in larger portion, by the mines on the Clinton hematite belt, which had been under recent development, while the Adirondack magnetite mines made the most favorable showing. The value of the iron produced in 1908 was \$2,098,247.

The production of clay materials aggregated in value \$8,918,863, as compared with \$12,688,868 in the preceding year. The decrease of about 30 per cent. was due both to a smaller output by the plants and to a reduction in market values. The combined output of brick, tile fireproofing and terra-cotta used for building purposes was valued at \$6,071,850, against \$8,909,392 in 1907. In 1906 these materials represented a value of \$11,063,433. The number of building

curb and flagstone, \$928,511; crushed stone, \$2,659,016; other uses, \$1,640,275. The output of slate, millstones and limestone used in making hydraulic cement is not included in the figures. Of the different kinds of stone, granite was the one to show a gain and this was accounted for by its increased use for paving blocks and crushed stone. The quarries of the State are able to supply almost every variety of rock for building and other purposes, though there is a large importation from other States.

The manufacturers of hydraulic cement contributed in 1908 a production valued at \$2,254,759. In 1907 the value amounted to \$2,971,820. Of the product last year 1,988,874 bbl., valued at \$1,813,623, consisted of portland cement and 623,618 bbl.,

TABLE 1. MINERAL PRODUCTION OF NEW YORK.

Year.	CARBON DIOXIDE.		CEMENT, PORTLAND.		CEMENT, NAT. HYD.

1908	1,100,128	2,071,533	23,675	104,799	9,005,311	2,130,736	70,739	697,390

brick made last year was 1,066,533,000, of which 817,459,000, or about three-fourths represented common brick from the Hudson river region. Along with the decline in building materials there was a large decrease in the ceramic industry, the value of pottery manufactures amounting to \$1,653,241, as compared with \$2,240,895 in 1907. The number of plants that were engaged in clay manufacturing of all kinds was 240, or two less than in 1907.

The value of the quarry products for 1908 was \$6,015,614, against \$7,890,327 in the preceding year, a falling off of 16 per cent. The total was divided according to the various uses into: Building stone, \$1,264,403; monumental stone, \$139,077;

valued at \$441,136, of natural rock cement. The latter industry has shown a steady decline for a number of years, due to general conditions in the trade. On the other hand the situation in the portland-cement industry may be expected to improve and there is every prospect that the State will soon have a much larger share in the domestic production than at present.

From the salt mines and wells there were obtained last year 9,005,311 bbl., valued at \$2,136,736. The showing was better, relatively, than in many other branches of the mineral industry; as compared with the figures for 1907 (9,657,543 bbl., valued at \$2,449,178), there was a falling off in production of less than 7

*Assistant State geologist, Albany, N. Y.

per cent. For many years the output of the State increased very rapidly, and it now amounts to about one-third of the total for the entire country. Onondaga county, where salt making was first introduced more than a century ago, still held the leading place last year, though most of its product was not put into marketable form, but was consumed for the manufacture of soda products. Livingston and Wyoming counties led in the production of rock and brine salt, respectively, for the trade.

The mines and quarries of gypsum contributed an output of 318,046 short tons, or nearly the same as in 1907, when it amounted to 323,323 short tons. The value of the different gypsum materials, including plaster of paris, wall plaster and gypsum sold in crude condition was \$760,759 in 1908, against \$751,556 in the preceding year. The gypsum industry has grown remarkably in the last few years, the output of the State having increased nearly ten-fold in the decade from 1898. With

The garnet mines in the Adirondacks were worked last year on a much reduced scale. The output of 2480 short tons, valued at \$79,890, was less than half that for 1907, when 5709 short tons, with a value of \$174,800, were reported. The decline may be ascribed to the smaller demand for abrasive materials during the year.

Crystalline graphite was mined in Warren and Saratoga counties. The output amounted to 1,932,000 lb., valued at \$116,100, against 2,950,000 lb., valued at \$106,951, in 1907.

The mineral springs of the State reported sales last year of 8,007,092 gal., valued at \$877,648, or about the same as in the preceding year. Saratoga county with the famous Saratoga and Ballston springs, contributed about \$175,000 to the total value.

Among the other mineral products of New York last year were apatite, carbon dioxide, clay, diatomaceous earth, emery, feldspar, marl, millstones, metallic paint, slate pigment, pyrite, quartz, slate, sand

ber, 1908, a new company to be called the Kyshtim Corporation, with provision for the necessary capital to carry on the timber, iron and copper industries of the estates.

"The Anglo-Siberian Company's assets consist of shares in the Perm Corporation and shares and debentures in the Kyshtim Corporation. The company holds about 43 per cent. of the issued capital of the Perm Corporation, which owns 521,574 Kyshtim Corporation shares. Therefore, this company has an interest equivalent to 224,000 shares of the latter corporation. There is a heavy debt on the estate, but the sale of timber with due regard to the proper system of forestry which is now enforced, is a permanent source of revenue for the payment of interest and amortization, and the charges on the estate are entirely provided for by the agricultural land and forests, leaving the working of the iron and copper deposits as free as if they were upon an unencumbered estate.

"The iron industry at Kyshtim has an output of various classes of fabricated products amounting to about 30,000 tons per year. Improvements in manufacture have reduced the costs and combined with alterations in methods will obviate the necessity of holding such large stocks of raw material, and consequent lock-up of capital, as has heretofore been necessary. The grading for the light railway connecting the copper mines at Soimonovsk with the main line at the town of Kyshtim is under way and the foundations are being prepared for the new buildings required for our copper-smelting plants. At one time it was intended to rush this work so as to start it at the beginning of next year, but it is now thought more prudent for technical and other reasons to defer the actual erection of the plant until the railway is completed, so that the material may be transported by it. The smelter, however, will start well within the period originally estimated by the engineers.

"The electrolytic plant started work in March, 1909, and is now converting into cathode copper and wire bars our own production of copper. A bore hole which has been driven on the Konikuhoff copper property has cut the lode 650 ft. on the dip below the line on which our engineer based his estimate of tonnage. The lode was found to be 9 ft. thick and will add materially to the reserve of the company, which was previously estimated at 500,000 tons. Another matter of much interest to the company is the proposed extension of the government railway from north to south through the whole of our western estate and touching the principal sheet-iron works at Niazepetrovsk, to which it will be of the utmost benefit."

Only 50 tons of tin ore, valued at \$12,500 were produced in the United States in 1908. In 1907 the output was 63 tons valued at \$15,200. The above data is from statistics of THE MINERAL INDUSTRY.

TABLE II. SUNDRY MINERAL PRODUCTION OF NEW YORK IN 1908.

Product.	Unit.	Quantity.	Value.
Building brick	Thousands	1,065,533	\$3,200,951
Pottery			1,653,241
Other clay products			2,064,671
Crude clay			18,341
Millstones	Short tons	4,697	11,605
Slate pigment			7,376
Mineral waters	Short tons	922	877,648
Sand and gravel	Gallons	8,007,092	1,130,291
Sand-lime brick			55,688
Slate	Thousands	8,239	111,217
Granite			367,564
Limestone			3,119,835
Marble			692,857
Sandstone			1,711,585
Trap			723,773
Other materials (a)			333,648
Total value			\$29,517,942

a Includes apatite, carbon dioxide, diatomaceous earth and marl.

the inexhaustible supplies afforded by the local deposits and the unrivaled facilities for reaching the principal eastern markets, there is every prospect that the production will soon reach even greater proportions.

The combined value of the petroleum and natural gas produced in the State last year was \$3,059,308 against \$2,536,349 in 1907. The quantity of petroleum taken from the wells amounted to 1,160,128 bbl., valued at \$2071,533, as compared with 1,052,324 bbl., valued at \$1,736,335 in the preceding year. The natural gas production was valued at \$987,775 against \$800,014 in 1907; the volume of gas amounted to 3,800,000,000 cu. ft. against 3,052,145,000 in the preceding year. The exhaustion of both the petroleum and natural gas pools does not seem to be imminent, judging from the records of production for recent years.

A product of which the State has almost a natural monopoly is fibrous talc, which is found in St. Lawrence county in extensive deposits of superior quality. The material is consumed mostly in the paper trade and is shipped to all parts of the country as well as to foreign mills. The output of ground talc last year amounted to 70,730 short tons, valued at \$607,300, and showed a good gain over the total for 1907 which was reported as 59,000 short tons with a value of \$501,500

and sand-lime brick, the aggregate value of which amounted to \$1,902,628, as compared with \$2,317,384 in 1907.

Anglo-Siberian Company, Limited

At a recent meeting, in London, of the shareholders of the Anglo-Siberian Company, Limited, which owns extensive timber, iron and copper interests in eastern Russia, Thomas Blair Reynolds, chairman of the company, in reviewing its work said in part:

"Early in 1907 the company secured an interest in an option for purchasing the Kyshtim Mining Works, owning large estates in the region of the Ural mountains. During the option period the proving of recently discovered copper lodes was undertaken, but it was found that the period of the option was not long enough to determine the value of the deposits of copper and an extension of the option was obtained and further capital provided.

"The Perm Corporation was thereupon formed for the purpose of taking over the rights and obligations of the option contract. Subsequently it was decided that the results of the investigations justified the exercise of the option, and accordingly the Perm Corporation formed in Novem-

Notes on Various Applications of the Elmore Vacuum Process

By A. STANLEY ELMORE.*

As the successful development and introduction of a novel process for the treatment of ores is a matter of general interest to metallurgists it is thought that the following notes may be of some value to those contemplating the erection of ore concentration plants. No detailed description of the process is called for here as full particulars appeared in the *JOURNAL* of May 11, 1907.

The scheme of treatment for a given ore is as follows: The ore is crushed wet to such a mesh as will reasonably liberate the particles to be recovered from the associated gangue. The pulp is then agitated with small quantities of oil and acid. The oil adheres to the metallic particles, leaving the gangue free from oil.

The pulp so prepared is then subjected to a vacuum (usually corresponding to about 20 to 27 in. of mercury), when the mineral will be found to have floated to the surface, leaving the gangue at the bottom of the vessel in which the operation was conducted; thus a very sharp separation is secured yielding a clean concentrate.

Like every other metallurgical invention the Elmore vacuum process has its limitations; however, its field of application is much wider than has been supposed by some engineers. Furthermore, it was supposed in the early days of its introduction that the apparatus for carrying the process into effect was necessarily complicated, expensive and delicate in working. Several years' experience in mills, treating large tonnages of ore under usual working conditions, with ordinary labor, has totally disproved some of these erroneous impressions.

Continuous workings, in some cases for periods of two years, have shown that the plant is practical, simple and substantial. The Elmore invention has found a wide application. Although much time has been occupied in establishing confidence in the process, it would doubtless have been much longer had not the company controlling the patents, placed a well equipped testing works at the disposal of likely users. These works are equipped with automatic samplers, as well as floors for hand sampling, and in all cases of testing, either on a small or large scale, the supervision of independent engineers has always been invited. In this way accurate data under working conditions are secured for the satisfaction of intending licensees.

It is interesting to note that in every one of the working plants quoted below, the orders were secured as a result of trials carried out at the testing works

ELMORE PROCESS INSTALLATIONS

Dolcoath Mine, Cornwall.—In certain parts of this mine the ordinary tin ore is found impregnated with varying proportions of sulphides, principally of copper. This ore is crushed in the usual Cornish stamp battery and passed direct to one unit of an Elmore plant. By this operation most of the sulphides are floated out and recovered as a high-grade copper concentrate, which contains, approximately 2 to 3 lb. of tin per ton. Practically all of the tin oxide is left in the tailings from the Elmore plant. These tailings are subsequently treated by Frue vanners in the ordinary way for the recovery of the tin oxide. The oil and acid used in the Elmore apparatus in no way injuriously effects the subsequent recovery of the tin. This plant was supplied to the Dolcoath company in March, 1907, and continues to yield satisfactory results, giving an extraction of over 90 per cent. of the copper contents of the ore.

Ramsley Mine, Devonshire.—The ore treated consists of a mixture of chalcopyrite and bornite with some chalcocite in a slaty micaceous gangue, containing about 2½ per cent. copper. It is crushed in stonebreakers, high-speed rolls, and Huntington mill in the usual way. The pulp is sent direct to one unit of the Elmore plant. The concentrates produced assay about 12 per cent. copper. The plant has been in operation about seven months and is to be enlarged shortly.

Dolgelley Mine, North Wales.—The ore consists of chalcopyrite with varying proportions of pyrite in a schistose gangue. The grade of the ore operated upon is usually about 1.2 per cent. copper, 0.08 oz. gold and 0.8 oz. of silver per ton. The ore is crushed by a reciprocating stonebreaker, followed by a California 20-stamp battery (1050 lb.) reducing it to 6-mesh. The pulp from the battery is sized on a 16-mesh screen and the oversize recrushed in a grinding pan. The pulp is then sent direct to three units of the Elmore plant and yields a concentrate of about 12 per cent. copper, 0.7 oz. gold and 7 oz. of silver per ton, the tailings assaying about 0.25 per cent. copper with small amounts of gold and silver.

Prior to the installation of the vacuum plant much money had been spent at this mine on various forms of water concentration machines. Owing to the extreme softness of the copper sulphides and the unusually tough character of the rock the loss in fines was always prohibitive, and such attempts were finally abandoned in favor of the vacuum plant which has been in continuous operation for two years.

The Zinc Corporation, Broken Hill.—The material is a zinciferous tailings from the local dressing mills treating the

well known Broken Hill ore. The gangue consists largely of garnet and rhodonite and has practically the same specific gravity as the zinc blende with which it is associated. Separation by ordinary water concentration is not possible on this material. The tailings on the dump are already fine enough for direct treatment in the Elmore plant; that portion which is too coarse is crushed in 12 grinding pans, and sized on improved revolving screens; the oversize is recrushed on six additional grinding pans. The average assay of the material operated on in this plant so far is zinc, 20 per cent.; lead, 5.75 per cent. and silver 8 oz. per ton. This yields concentrates assaying zinc, 43 per cent., lead 11 per cent. and silver, 17 oz. per ton. It has been found that if these concentrates be dried and subjected to a sufficiently high temperature to drive off the small quantity of oil which it contains, the de-oiled concentrate may then be mixed with water and passed over Wilfley tables yielding a zinc product assaying zinc, 46.5 per cent. Lead, 7.35 per cent.; and silver 16 oz. per ton; and, a lead concentrate assaying lead, 58 per cent.; zinc, 15 per cent. and silver 39 oz. per ton. The value of the final residues from this Elmore plant depends to a great extent upon the more or less oxidized condition of the mineral in the material operated upon (much of the material on these dumps has been exposed to atmospheric oxidation for many years). The following may be taken as fairly representative: Zinc, 3.5 per cent.; lead, 2.2 per cent. and silver 2.2 oz. per ton.

Careful determination has shown that a large part of the metal contents is present in the form of oxidized compounds. The actual recovery secured by the Elmore plant at the Zinc Corporation may be taken as follows: Zinc 90 per cent.; lead, 73 per cent. and silver, 85 per cent.

The 16-unit plant was installed only after most exhaustive trials had been carried out with one unit. The mill handles about 18,000 tons per month and produces about 7000 tons of concentrates. This mill, which has been in continuous operation for 15 months, gives a higher capacity, better grade of concentrate and greater percentage of extraction than was indicated by the trials with the one unit plant.

Edmundson Copper Mine, Africa.—The ore consists of chalcopyrite very finely disseminated through a feldspathic gangue. It is crushed by stonebreakers and Holman pneumatic stamps and passes directly to a two-unit Elmore plant. The ore assays about 2.5 per cent. copper and yields a concentrate assaying about 22.5 per cent., with a recovery of 85 per cent. of the copper.

Garpenberg Mine, Sweden.—The ore consists of a quartz gangue with magnetite, chalcopyrite and pyrite. It is low grade, assaying about 1 per cent. copper.

*Chairman, the Ore Concentration Company, Ltd., 4 Broadstreet Place, London Eng

The crushing plant consists of a stone-breaker followed by rolls, the product going to jigs and tables in the ordinary way. The table tailings, together with the jig tailings after recrushing in wet ball mill, are treated in the vacuum machines. One unite was tried first; later two more were installed, and one more is about to be erected.

Traag Mine, Norway.—The ore carries both zinc and lead associated with a heavy gangue. After crushing in stonebreakers and Huntington mills the pulp is treated on Wilfley tables for the production of a lead concentrate. The tailings from the Wilfley table go to the single unit Elmore plant which yields a concentrate assaying about 58 per cent. zinc. The zinc sulphide in the ore is a friable, resin blende and, in consequence of excessive sliming coupled with heavy gangue, was found to be practically impossible of collection by ordinary water concentration appliances.

Hadeland Mine, Norway.—The ore consists of zinc blende associated with a large proportion of magnetite and some spathic iron. Trials with various water concentration appliances had all proved quite unsatisfactory. The ore is crushed in Krupp ball mills and sent direct to the Elmore plant. It yields a high grade concentrate with a very satisfactory extraction. The company, after having operated the one-unit plant for about six months, has ordered three additional units.

Telemarken Mine, Norway.—The ore consists of chalcopyrite and bornite in a gangue composed of hornblende, micaceous schists and hard quartz. The crude ore from the mine is hand sorted. The ore thus enriched contains about 4.5 per cent. copper. It is crushed in a No. 5. Gates crusher, followed by Ferraris wet ball mills. The pulp is sent direct to a three-unit Elmore plant, from which concentrates assaying about 26 per cent. copper are obtained, the final tailings containing only 0.20 per cent., thus giving a recovery of about 95 per cent. of the total copper content.

Sulitelma Mine, Norway.—The ore carries copper in the form of chalcopyrite, associated with a large proportion of pyrite, the gangue being micaceous schist. As the ore comes from the mine it is crushed in large stonebreakers and carefully hand sorted. The clean lumpy pyrite is sold to sulphuric acid works where it is roasted for its sulphur. The cinder is subsequently treated for its copper contents. The low-grade ore left after hand sorting is crushed with rolls and passed to jigs, tables, and vanners.

This water concentration plant is of first class design, operated with good labor and under excellent technical supervision and control. Nevertheless, the loss of copper in the tailings is heavy owing to the particularly friable nature of the cop-

per pyrites. The residues from this water concentration plant vary in grade from 1 to 1¼ per cent. copper, associated with pyrite and some magnetite. The water concentration mill handles about 800 to 900 tons a day and produces about 500 to 600 tons a day of tailings. These tailings are an unusually dilute pulp, the proportion of water to solids being about 100 to 1. At present about 400 tons of solids per day with the above proportion of water, are sent to the twelve-unit Elmore plant for the recovery of the copper. Arrangements are being made which will enable all of the tailings from the water concentration plant to be sent to the Elmore plant.

The small part of the tailings, too coarse for treatment direct in the Elmore process, are recrushed by Heberle ball mills. The pulp, which as before stated is associated with an immense amount of water, is run into large settling tanks to get rid of the excess of water. Concentrates varying from 6 per cent. up to 11 per cent. of copper (the grade depending upon the proportion of iron pyrites) are produced. The final tailings assay 0.2 per cent. copper. The great bulk of the material handled by the vacuum machines consists entirely of slimes. An average of about 150 tons of concentrates per week are produced from waste material which had previously been discharged direct to the tailings dump.

Saxberget Mine, Sweden.—The ore is a mixed zinc-lead-silver material which, after crushing in stone-breakers and wet Gröndall ball mills, is treated on tables for the recovery of the lead. The lead recovery by this means, however, is not good, and consequently the tailings from the tables, in addition to the zinc, contain notable proportions of lead and silver. Various attempts have been made previously to treat these tailings but without success. The Elmore plant is now producing mixed lead-zinc-silver concentrates which are subsequently smelted in an electric furnace.

Each unit of the plants represented above may be assumed to be treating 40 tons of ore per 24 hours equal to more than half a million tons per annum. It is interesting to note that in every instance these plants are working with the ordinary class of labor available at the several mines. They have been in operation for periods of time up to two years, and in each case are operating independent of any supervision by the company controlling the patents. It may therefore be reasonably assumed that the Elmore vacuum process has now taken its place definitely among recognized methods of ore treatment.

Attention is particularly directed to the variety of ores which are being treated regularly on a large scale, and to the still much greater variety of ores which have been tested both on a large and small scale at the testing works. Special emphasis

is laid on the great variety of crushing machinery which is employed with different ores in the various mills in connection with the Elmore process, and to the fact that plants are in regular operation in such extremes of climate as are found between Broken Hill, New South Wales, where the summer temperature reached 110 deg. F. and the Sulitelma mine which is 180 miles north of the Arctic circle where a winter temperature as low as -37 deg. F. is usually recorded.

Antimony in China

According to a recent report by the British consul at Changsha, the increase in the export of crude antimony and the decrease in the export of ore in 1908 were both noteworthy. The local notables who control the antimony works are in touch with London, and are kept fully informed as to the prices ruling in the London market. It seems probable that the export of ore will continue to decrease, owing to the erection of new machinery and the better handling locally of the ore, and that the export not only of crude, but of refined antimony will steadily increase.

The increase in the export of crude is, no doubt, due to the presence of a foreign buyer in Changsha. The old difficulty still exists of inducing the sellers to realize the binding nature of a contract, but constant personal contact between the native seller and the foreign buyer ought, with patience, to remove this serious obstacle to a satisfactory working basis, and it seems likely that in the future contracts will be more punctually fulfilled.

The price of crude, Changsha sales, varied from £10 13s. 4d. to £11 6s. 8d., and of ore from £4 13s. 4d. to £6 13s. 4d. It is hoped with the new machinery to produce refined antimony containing at least 99.6 per cent. and possibly 99.8 per cent. antimony. The relative value of refined to crude will be about £26 13s. 4d. to £10 13s. 4d. per ton.

During the past years the ore in Changsha has been so crudely smelted that waste ashes have been found to contain 30 per cent. antimony; many thousands of tons of such ashes have, from time to time, been thrown away, and money has been made by at least one enterprising foreigner who bought up all the ashes he could. This form of speculation is, however, now at an end.

Another point should be noted. In the past low-grade ores have been rejected owing to the imperfect furnaces in use, but with the improved machinery all low-grade mines should also become valuable and the export of antimony be greatly increased. A foreigner, well qualified to give an opinion, states that the richer ore found in Hunan is only equalled by one mine in France.

Geology of the Yellow Aster Mine, California

Remarkable Ore Deposits in Granite at Randsburg, Kern County,
That Have Produced about \$6,000,000 in Gold. Discovered in 1895

BY WILLIAM H. STORMS*

The consolidation of mining claims owned by the Yellow Aster Mining Company, of Los Angeles, Cal., constitutes one of the most important gold-mining properties of the West. The mines are situated in the Mojave desert, Kern county, California, about one-half mile south of Randsburg.

The discovery of gold in the district was made in 1895 by C. A. Burcham, Fred M. Mooers and John Singleton, who came into the region from the dry placer camp, at Goler, where they had met with indifferent success. The first discovery of gold was made in the dry sand of a gulch which cut the outcrop of the gold-bearing

known as Butte hill. The group of claims to the south, on Yellow Aster hill, developed year by year until the consolidated claims, known as the Yellow Aster mine, became an important and productive gold mine.

A REGION OF HORIZONTAL SCHISTS

For several miles about the village of Randsburg, the rocks consist chiefly of a series of granitoid schists, comprising both micaceous and hornblende varieties. In some parts of the region typical amphibolite schist occurs. The hornblende schists are often fissile at and near the surface, having distinct schistose

Among these theories is the possibility that the rocks comprising the schists were, at one time, buried so deeply that the tremendous pressure of the superincumbent mass induced a condition of schistosity.

Another theory, and a more probable one is that schistose conditions have been produced by the proximity of a huge batholith (probably granite) that may underlie the region. Still another theory conceives that the schistose and semi-schistose structure is due to the rocks having originally been deposited as a series of flows. This latter supposition seems improbable, as none of the rocks are of volcanic type, but of granitic character.

FIG. 1. YELLOW ASTER HILL FROM THE NORTH; 100-STAMP MILL AT THE RIGHT; 30-STAMP MILL AT THE LEFT

veins of the Yellow Aster hill. The dirt was concentrated in a dry-blowing machine. Soon after this the veins were discovered and development proceeded as rapidly as the isolated situation of the property would permit.

The output of high-grade ore from the various mines about Randsburg early attracted much attention. For the most part, the veins proved to be rather short and narrow fissures in micaceous and hornblende schists, and the first few years of active mining rapidly depleted the smaller veins on the ridge, north of town.

structure. These typical schists are found interbedded with layers of granite rock 4 to 5 ft. in thickness, possessing little or no trace of schistosity. These bedded schists extend in a northeast-southwest direction, a southwestern extension of the Slate range, although wholly detached from the latter range of mountains.

ORIGIN OF THE FLAT SCHISTS

That horizontal schists extending over any considerable area are unusual, will be readily admitted. Several theories to account for those about Randsburg have been advanced by prominent geologists.

The only remaining tenable theory is that the schistose structure may, to some extent, represent original sedimentation; and, that these, now crystalline schists, were originally horizontal sedimentary beds, which have been brought to an extreme state of alteration by pressure, still preserving traces of their original horizontality.

Personally I favor the theory of the batholith, which, in my opinion, lies at no very great depth beneath the present surface. To some extent the topography of these hills is influenced by the character of the rocks, the slopes of some of the hills conforming to the dip of the schists.

*Mining engineer, Los Angeles, Cal.

THE SURROUNDING REGION

Northeast of Randsburg, 3 or 4 miles, is an eminence known as Red mountain, which consists entirely of volcanic rocks—rhyolite, tufa and tuffaceous-breccia, but so far as known, no ore deposits of any description exist in this volcanic area. Less than a mile east of Randsburg, are large intrusions of granite, in which are included several irregular masses of limestone. These were probably torn from an older formation lying beneath, but which is unknown elsewhere in the vicinity of Randsburg. There are limited occurrences of quartzite and dense jasperoid

Aster mine; a further supply being obtained from other deep wells sunk six miles northeast of Randsburg. Goler lies at the mouth of a cañon cutting a north and south range of rugged hills, which consist mainly of schist. These schists are of a different type from those at Randsburg and vicinity, being evidently the result of the alteration of various greenstones. Igneous intrusions of huge dimensions are not uncommon in these hills.

South of Randsburg schistose rocks extend for many miles, and in them are known to be numerous gold-bearing veins,

masses lifted the schists from their flat position into a dome, but they have thrown them into a series of sharp folds, some of which appear near the northern base of the hill, east of Main street, and others in the cañon west and southwest of Randsburg. These folds afford additional relief from the tremendous compressive stress resulting from the repeated intrusion by a series of remarkable fissures occurring in Yellow Aster hill, along all of which a greater or less amount of movement has taken place.

The accompanying sketch map, Fig. 2, of the Rand level, which is at present the main working level of the mine, shows the distribution of the most of these fissures, and the relations to one another, and also, to some extent, to the various orebodies.

The footwall fissure—seemingly the only one that is absolutely continuous, so far as known—at the west end of the property in Olympus claim, has a strike a few degrees north of west, dipping about 30 deg. to the north. It runs easterly, gradually turning in a broad, sweeping curve to the south, until in a distance of 3000 ft. it strikes directly south, dipping 35 deg. east. This fissure is indicated on the map, and is found at several points in the mine workings and in surface cuts. It is generally accompanied by one or two feet of tough, putty-like gouge. The sweeping curve of its strike from nearly east-west to due south is somewhat unusual.

There are other fissures in the southern area of the property, the more important of which are indicated on the map, but these fissures seem to be a series of fractures following a common direction and overlapping each other, rather than continuous fractures.

What is commonly called the hanging-wall fissure is not such in reality, for orebodies occur both above and below. This fissure, known as the Jupiter, is also indicated on the map. In the west end of the mine the strike is nearly east-west, almost parallel with the footwall fissure, dipping north 20 to 25 deg., but becoming somewhat steeper toward the east, and with depth. Its dip is 35 deg. on the Rand level. This fissure and the footwall fissure are not over 30 ft. apart at the surface, in the west end of the mine. They separate rapidly eastward.

Proceeding along the Jupiter fissure, there may be observed numerous subsidiary fissures, which are part of the system of fractures due to the stress that produced the main fissures. Going eastward the Jupiter fissure also swings around to the southward, finally taking a more abrupt bend than the footwall fissure, eventually having a strike somewhat west of south, and uniting with some of the more important fissures in the interior portion of the area. The dip of this fissure is almost uniformly 35 deg. on the Rand level, but is somewhat less both above and below. At 400 to 500 ft., on the incline, below the Rand level, the dip

FIG. 2. SKETCH-MAP SHOWING FISSURE SYSTEM ON THE RAND LEVEL OF THE YELLOW ASTER MINE

rocks nearer town, particularly on the north slope of the ridge known as Butte hill, which, with the limestones, indicate sedimentary origin. Four miles east of Randsburg, dikes of pegmatite cut the schists. These dikes have, among other constituents, ores of tungsten—notably scheelite, which has been profitably mined in the Atolia mine.

West of the Randsburg district is a desert valley about six miles in width, on the farther side of which is Goler, the noted dry placer camp. Several deep wells sunk here, on what is presumed to be an ancient gravel channel, furnish the principal water supply for the Yellow

some of which have been profitably exploited.

YELLOW ASTER HILL

The hill in which the Yellow Aster mine is situated is among the highest of the range. This hill is the result of a dome-like uplift of the flat schists previously described. The schistose rocks, originally nearly horizontal, have been intruded by numerous dikes, large and small, and these intrusions have caused the older rocks to be lifted into a dome, the effect extending for thousands of feet in all directions from the center of disturbance. Not only have the intrusive

ore. Great stopes have been opened on the extension of this orebody, both above and below the Rand level.

About 100 ft west from the west end of the stope just referred to, begins another large orebody, but belonging to an entirely different series of oreshoots. Huge stopes have been opened on the Rand level, also above and below it. In all of these stopes the limitation of stoping has generally been determined by commercial considerations, excepting where the ore limit has been sharply defined by a fissure or abrupt change in the character of the rock, clearly discernible by the eye. The east stope on the Rand level, for instance, is sharply defined on the hanging side by a wall, although this fissure is one showing little or no movement. Over most of the area covered by the exposure of this wall there is little or no gouge, while on the footwall side the gold contents stops with no apparent change in the appearance of the rock. Throughout the mine there still remain large blocks of ore in the immediate vicinity of the principal stopes which will admit of little or no profit if mined by stoping and square-setting, timber costing over \$40 per M as delivered, and over \$50 per M set up in the mine. However, there is little doubt that much of this ore could be profitably mined if the open-cut system were applied to it. Development is resulting in the discovery of new orebodies in various parts of the mine, the diamond drill having been found particularly useful in searching for new masses of ore.

DISTRIBUTION OF THE ORE

To the casual observer the distribution of ore in the Yellow Aster mine appears to be extremely erratic and haphazard. Yet when the general map of the mine workings is studied it is found that nearly all of the most important orebodies belong to one of several systems or groups, each following an independent trend. Then there are orebodies apparently isolated, but which may later be found to belong to separate systems, the relations of which will be better understood by more extensive development, although there are already over 16 miles of underground workings in the mine.

Of the two important oreshoots mentioned, the most extensively mined is that lying to the east of a line striking about north 25 deg. east and approximately through the two shafts indicated on the sketch map, Fig. 2. This oreshoot, or more properly, series or succession of oreshoots, outcrops at the surface on the south slope of Yellow Aster hill near the west end of the property, where it forms a large body of low-grade ore. In its downward dip and trend it lies east of the line mentioned, its trend being about north 60 deg. east. Much of the ore mined from this succession of orebodies was very profitable.

The other large orebody appears, or did

appear, at the surface near that just described, but the upper portion has since been removed in the open cut or "glory hole." This orebody has a trend about north 15 deg. east, so that with depth these two great ore shoots became widely separated. In many respects these two orebodies are similar, particularly as to their size, form and manner of occurrence.

At least three other separate series of orebodies have been developed in the vicinity of the Jupiter wall. These are known as the Midway, the Buffalo and the Homestake. Most of the ore in the Midway series lies above the Jupiter wall, though some of it occurs underneath. At the Buffalo the greater part of the ore thus far developed lies underneath the fissure. In the Homestake-Hunt series is the Christmas stope above the Jupiter wall, but near the surface, on the Rand level, a rich shoot was found under and in close proximity to the wall. This shoot is in direct line with the Homestake and Christmas and may very properly be considered as belonging to the same series. It should be understood that none of the orebodies mentioned as connected with the Jupiter wall have any relation to, or connection with, the large masses of ore in the central portion of the mine.

In the southeast part of the mine and entirely separate from the orebodies already mentioned, are several other shoots, some of which have been very profitable. In this part of the mine, and also toward the west end are extensive bodies of low-grade ore which undoubtedly will be mined at a profit at some time in the future.

An interesting fact in connection with this mine is that if a cross-section were taken every 100 ft., no two of the sections would be alike, even those at adjoining stations. Most remarkable changes take place often within a few feet.

In the northeast part of the mine, and about 300 ft. below the surface is a stope known as the Hobo. On the 200 level the ore is about 4 ft. in width. The hanging side is defined by a good wall; the footwall is irregular. The hanging-wall is nearly vertical. The footwall slopes back with varying angle, until, 60 ft. above the level, the slope is about 20 ft. wide. Just above this the schist swings over the granite-porphry from the hanging-wall, and the ore following it, rapidly thins out and becomes a mere seam a few feet above the next level.

VERTICAL ZONES OF IMPREGNATION

In addition to the large ore-deposits already referred to, there also occurs, in the granite-porphry, a series of nearly vertical zones of gold-bearing rock which have no walls. These are indicated on the map, Fig. 2, and section, Fig. 3, by the name—the Price, Vertical and Hole-in-the-Wall. These peculiar occurrences are in no sense veins or orebodies of definite form, being merely a series of reticulated cracks

or seams occurring along a common direction, such as may be observed in granite. A slight brownish stain of iron oxide is about the only indication of mineralization noticeable in this rock, and much of it shows little sign of oxidation. Occasionally a little secondary quartz and sometimes pyrite is present. The granite in these zones presents no evidence of movement or shearing, but coarse gold occurs in these zones of fracture and impregnation, and they have proved very profitable, the Price and Vertical being particularly high grade. These veins, as they are called, have been stoped in the ordinary manner, from 4 to 12 ft. wide, and square sets placed in the wider portions.

ORE IN THE SCHIST

Ore rarely occurs in the schist. In almost every instance where the gold-bearing granite-porphry is interrupted or cut off by schist the gold disappears. A remarkable exception occurred near the summit of the dome where a small fissure cut the schist. This vein carried much limonite and was rich in gold. The rock was soft and decomposed at the surface, and was run through a dry-blower with most satisfactory results. This place is known by the peculiar name "Instinct," the discoverer claiming that it was by instinct he found the orebody.

A PROBLEM IN MINING

The orebodies do not always reach the surface, some of the larger ones being overlaid by the horizontal schist from 20 to 80 ft. in thickness.

Some of the older stopes have caved and the ore remaining can be recovered only by stripping the overburden which is, generally speaking, on the south side of the cut.

By doing this much ore would become available at a cost which will admit of a profit on the operation. Late accounts from the mine state that stripping operations have actually been commenced, and the great cut will consequently be broadened and later deepened.

China is showing much interest in mining affairs, according to the *Far Eastern Review*. The government at Peking has directed the governor of Chinese Turkestan to investigate and report on the copper deposits of Kucha and Paichang with a view to developing them along modern lines.

The output of vanadium in the United States, according to statistics of THE MINERAL INDUSTRY, increased last year. In 1908 the production was 64,800 lb. (\$162,000), while in 1907 it amounted to 41,000 lb. (\$102,500).

The production of tin in Queensland during 1908 (*Queensland Gov. Min. Journ.*, April 15, 1909) was 4825 tons, valued at £342,101. This is a decrease of 315 tons, as compared with the production of 1907.

Automatic Dumping Skip for Vertical Shafts

Design and Operation of a Self Dumping Skip for Hoisting Either Rock or Water. Hoisting Mine Water Compared with Pumping

BY GEO. C. MC FARLANE *

In the accompanying sketches, Fig. 1 illustrates a skip that can be used for hoisting rock and water from a vertical shaft. The body of the skip rests on a bottom axle, swung from stirrups that fit the guides and are suspended from the draw-head by side rods on either side of the guide strips. A couple of short angles riveted to the sides and just below the top binder form guide shoes to keep the skip vertical.

In case the skip only has to dump at one landing stage on top, two dumping rollers on a side and a dump track similar to that shown in Fig. 4 are all that is required. If it is desired to dump ore, rock and water at different landing stages at the surface, a three-roller dump and a cross-over style of dump guides like that shown in Fig. 2 will be required at all except the top dump.

The front and rear roller and the shoe angles project $2\frac{1}{2}$ in. beyond the sides of the skip and the middle or outboard roller projects $4\frac{1}{2}$ in. The side rods clear the sides of the skip 3 in. and at the dump the shaft guides are cut away to a depth of $2\frac{3}{4}$ in., so the shoe angles and rear roller can swing through side rods and shaft guides at the dump. If not used for hoisting men the skip can be coupled up short to the draw-head, but if it is desired to hoist men also, long side rods can be used so the men can stand upright on a light wood grating thrown across the top of the skip and grasp a hand rail bolted to each cross piece of the draw-head. Covers and safety dogs that dig into the inner face of the guides can be readily attached to the draw-head to make the skip safe for hoisting the men.

The object in designing this skip was to obtain a skip that would dump rock and water and also dump quickly. In this respect the skip is faster than the skip used in inclined shafts because the dump is positive and can be negotiated at high speed, throwing the load out square and clean and not slopping back in the shaft. In a sense it is a modification of the Russell type of self-dumping cage which has been used with good success in the Saginaw field for nine years. This type of cage is outlined in Fig. 5. The principal feature is the hook for raising the car doors as the car is tipped into the dump. The hook is pivoted between two pieces of flat iron about 5 or 6 ft. long suspended from a light cross-arm one end of which projects into the cageway. As the cage

throws the car into the dump a roller on the hood of the cage strikes the cross-arm and raises the hook which has just entered a loop in the car door. The hook and cross-arm are steadied in place by light chain side guys. Should a car door jam and refuse to raise, the shank of the hook will swing through the flat bars that grip it and release the hook.

A self-dumping cage has only to swing through an angle of about 50 deg. to discharge its load; a skip, on the other hand, has to be swung at least 135 deg. to dump rock readily. By the addition of the outboard roller to the skip, it is prevented from swinging back in the shaft when it

is necessary to put in field or auxiliary pumps to collect the water at the main sump there would be little economy in running bailers in the shaft.

In opening up steep pitching lode mines by vertical shafts the water could of course be easily drained to the main sump by gravity and in such cases the money usually spent in buying pumps, pipe, and a geared hoist, could be invested in a larger first-motion hoisting engine and balanced skips. The compartments should be large enough for $5\frac{3}{4}$ -inch guide strips, i.e., a 6×6 in. strip, dressed on four sides. White pine or a similar fine straight-grained wood is perhaps the safest for guides, as the safety dogs have a better chance to gouge in and catch if the cable breaks. Hard maple wears smooth and is more durable than pine. The shoes and stirrups should fit the guides with not more than an $\frac{1}{8}$ or $\frac{3}{16}$ in. clearance. When the strips wear away $\frac{1}{4}$ in. new guides should be put in. If the guides are badly worn the skip will oscillate and wobble and not strike the dump square. As there is a good deal of side pressure on the stirrups as the skip is dumping, it is a good scheme to put 6-in. channels back of the guides at the dump. The guides should be given good alignment and preferably should be bolted through shims or spacing blocks so they can be easily straightened in case any of the sets take a slight squeeze.

Fig. 2 shows a cross-over arrangement of dumping guides, which permits of the skip discharging water just above ground level and by throwing the switch, ore or rock can pass through to a dump higher up in the shaft-house. When the switch is thrown back the skip is carried over the cut-away portion of the guides by two of the rollers, the outboard roller passing between the legs of the channel shown in the sketch. If it is desired to hoist a large volume of water, balance tandem skips can be used and unloaded in a two-way dump similar to the arrangement shown in Fig. 4, or longer bottom side rods can be used and both skips thrown one way. The lower skip can be fastened to the stirrups of the upper one by keying through the side rods and fastening the keys with cotter pins; then the bottom skip can be quickly detached and left in the sump and ore hoisted with the top skip. The horns of the water dump shown in Fig. 4 can be hinged to swing out of the way; then, by slipping in a filler in the cut-out of the guides, the

The Engineering & Mining Journal, N.Y.
FIG. 1

swings down below the horizontal. As the skip tips into the dump the outboard roller slides in under the guard rail and as the skip kicks back, the roller is canted up high enough to catch the outboard track and ride up it. With this device the skip can be over-wound 8 or 10 ft. without causing trouble.

HOISTING MINE WATER

Where conditions are suitable, this kind of hoisting gear can be used for raising the mine water as well as the ore and waste. To bail water cheaper than it can be pumped, the rigging should be put in at the start of a new operation, and only in case it was reasonably certain that the shaft could be run down vertically and the workings laid out to drain the water to the shaft bottom by gravity. If it

*Mining engineer, 312 Bealinger building, Saginaw, Mich.

ore loads can pass through to the ore dump.

Fig. 3 shows a sump arrangement by which single skips can be tipped and filled in the sump. To accommodate this layout the sump must be about 4 ft. wider than the rest of the shaft. Tandem bailers are ideal because they have enough weight to sink and fill over the rim, and they fill in a second, where a valve bottom bailer requires anywhere from 3 to 8 sec. to fill.

All the dumping tracks or guides shown in the sketches, except the switch, which is cast iron, are made of hardwood, ironed off with $\frac{3}{4}$ -in. flat iron and securely bolted to the girths and buntions of the cageways. The patterns are struck off on a floor. First chalk down a line for center line of guide, then lay off a front dump circle of any desired radius, say from 12 to 20 in. Then make a templet of the skip showing axle, guide rollers and shoe angles. The back curve can now be scribed by rolling the templet on the front circle while keeping the axle center on the chalk mark that defines the shaft-guide center line. Care must be taken that the shoe angles clear the front circle.

HOISTING WATER VS. PUMPING

It is conceded that a water hoist is rather more economical of power than the average run of small mine pumps. This was brought forcibly to my mind a couple of years ago at a little mine in California. A pump was lifting water from the 300

'level. When firing for the pump alone. I found it took a cord of dry pine wood, evaporating 1000 gal. of feed water, to pump 22,000 gal., or 92 tons of water. After resuming hoisting, I had the engineer of the night shift (on which no pumping was done) keep tab of the wood

used, and found we were hoisting 80 to 90 tons of muck and ore from the 300 and 400 levels with a trifle over half a cord of wood; showing that the little hoist was nearly twice as efficient a machine as the mine pump.

A good hoisting engine, properly handled, has several advantages over a pump for lifting water. In the first place it has a small coefficient of internal friction. I have often noticed that the weight of a couple of men on one cage will start a (20-x 30-in.) first-motion balanced hoist when the brake is thrown off and the throttle is closed. As the cages alone weigh nearly two tons apiece, the friction loss must be very low. The engine, being close to the boilers, gets fairly dry steam. On the other hand, a pump has a big friction loss in the barrel, because the barrel gets scored more or less with even moderately dirty water, and the segments have to be screwed up tight against the packing to hold 10 or 15 ft. of vacuum. There is quite a loss in the long steam line both from pipe friction and condensation. In a long steam line with several elbows and other obstructions, the globules of condensed water also drag down the pressure of the steam, for every time they bunt into an elbow they nearly stop until again whipped up by the steam. Besides, there is a small per cent. of loss in the friction of the water column and more or less leakage through the valves.

In a mine depending on pumps to handle the water, one pump at least must

The Engineering & Mining Journal, N.Y.
FIG. 2

FIG. 3

FIG. 4

The Engineering & Mining Journal, N.Y.
FIG. 5

always be kept in reserve, so that one of the others can be repacked and repaired.

If mine pumps are dispensed with, and the water raised with automatic bailers in connection with the regular ore and rock hoisting, there should be quite a reduction in the fuel used. The best feature of a water-hoisting plant, in my opinion, is that there need be no worry over flooding the mine should a big body of water be tapped or should the pumps be submerged by any accidental stoppage, such as the playing out of a boiler or a temporary interruption of the fuel supply. If the water temporarily gets the start of the water hoist, the engine can soon bring it down to the sump. Should the emergency arise, I am satisfied a good first-motion hoist with tandem bailers could pull water at a tremendous rate, because the skips will fill and dump almost in a second and as there is plenty of leeway on which to stop, the engine could be run at high speed.

I have occasionally timed engineers, who could pull a car of coal from the bottom and put it into the dump in from 9 to 11 sec., a distance of 250 to 275 ft., and there would be only about 12 in. to play on at the dump. I noted one hoist runner a few years ago who handled the engine almost entirely with the reverse lever when the coal was coming fast. At the tap of the bell he would throw it over and hook it on center before the cage shot into view above the ground level. As the tippie floor was 50 ft. above the ground the cage traveled on its own momentum possibly 60 or 70 ft. Of course the descending empty cage helped it along some, but even allowing for the velocity of the falling cage, the load must have been traveling at the rate of 40 ft. per sec. in the middle of the hoist.

In these shafts the guides did not vary $\frac{1}{4}$ in. from the perpendicular in their entire length. If the shaft is crooked or has a couple of short kinks in it, it would not be advisable to attempt high-speed water bailing. When a hoist is operated at a fairly high speed and handled mainly with the reverse, it is a very efficient machine. Wire drawing the steam with the throttle and choking the engine off with the brake and stopping 15 or 20 sec. between winds, allowing the cylinder to cool off, cuts its efficiency down quite perceptibly.

Sampling Ores from the Cobalt District

A. A. Cole (*Can. Min. Inst.*, 1908) describes the sampling of the silver-cobalt ores from the Cobalt district, Ontario, as practised at Copper Cliff. The difficulty in sampling these ores is caused by the occurrence in them of large amounts of metallics composed of native silver or silver-arsenic alloys. The ore is usually

shipped from the mines in bags and is weighed in drafts of 10 bags each as it is unloaded from the cars. The contents of the bags are dumped into a Buchanan jaw crusher and the bags weighed for taring purposes.

One small shovelful representing each sackful is taken of the crushed ore as a moisture sample. This moisture sample is coned and quartered to about 100 lb., and then crushed with a small Allis-Chalmers laboratory jaw crusher. Four samples of about 11 lb. each are then cut out and dried in a steam oven for about 20 hours at a temperature of about 80 deg. Centigrade.

All of the moisture sample is returned to the main portion and the whole passed through an Allis-Chalmers ball mill. In case the ore is wet it undergoes a preliminary drying on steam-drying plates before being fed to the ball mill. The balls in this mill are of hardened steel and have a weight of 1 $\frac{1}{4}$ tons. The ore is ground until it passes a 20-mesh screen, sieving tests showing that 50 per cent. will pass a 100-mesh screen and 80 per cent. a 50-mesh screen. The capacity of the mill is 1.5 tons per hour.

One-tenth of the ore as it is discharged from the ball mill is cut out by a 27-in. Snyder automatic sampler. The sampler is chain driven to prevent slipping and makes 25 r.p.m., giving 3000 cuts per hour for 1.5 tons of ore, or one cut for every pound of ore. The sample and rejected portion are weighed and this weight less the moisture is used in settlement. The original weight less moisture should check this latter weight and as a rule does. The moisture sample on the milled ore is obtained by taking a portion from each paulful of the sample by means of a tube sampler.

The main sample is mixed on the concrete floor of the sample room by shoveling it over twice. After coning and quartering once, the two halves obtained are treated as independent samples. Each of these samples undergoes the same treatment. They are first cut down by coning and quartering to about 100 lb. From this point the cutting down is done with a Jones sampler until two portions of about 20 lb. each are obtained. One of these portions is sealed up as a reserve sample and the other thoroughly dried and ground in a Sturtevant disk grinder until the fines pass through a 100-mesh screen, leaving the metallics bright and clean on the sieve. Sometimes an Alabé pebble mill and a Hance drug mill are used to assist in the grinding. The metallics and fines are weighed and sampled separately, the fines being first mixed by an hour's revolution in the pebble mill. The large metallics that remain in the large ball mill are removed at the end of the run, weighed and melted into bullion. The resulting bullion, slag and dross are weighed and sampled, the slag and spriss being sampled together.

The time of sampling is three days for a 30-ton lot. The results should be accurate as the method is based on the best practice.

London's "Kafir Boom"

"The revival in Kafir shares," writes a Stock Exchange correspondent to the *London Economist*, "which has led to the present boom among nearly all the sections of the South African market, may be ascribed in part to the East Rand Proprietary Mines, Ltd. It is less than a year ago that the East Rand consolidated the six subsidiaries, Driefontein, Angelo, New Comet, Cason, Cinderella and New Blue Sky Companies, together with the H. F. Company, the Angelo Deep, the Hercules, part of the Driefontein Deep and various other claims and interests. This necessitated the increase of the capital to £2,500,000, of which £2,405,897 was issued, the total number of shareholders being something like 16,000 people.

"The amalgamation, pioneer of the many which have since become so popular, rather staggered the market, and the advantages claimed for it were by no means generally conceded. But the monthly output from the consolidated company left no room for doubts, at any rate, as to the immediate wisdom of the policy. The profits for each of the past four months, from January to April, have been returned at £101,064, £101,666, £103,892 and £104,283, a total of £410,911, or at the rate of £1,232,733 for the year, without taking into account progressive expansion, such as the character of the figures just quoted may justify.

"That such statistics have had a great effect in assisting in the production of the Kafir boom nobody will question. The successful carrying through of the East Rand amalgamation gave the signal for the launching of various other similar schemes, which have certainly played their part as factors in the market revival. The boom progresses, and the coming settlement will be one of the heaviest the Kafir market has been since the pre-peace days of January-June, 1902. The provinces have been large buyers, the Germans and the French even larger, and the Continental purchases are mostly lifted from the market—not carried over—thereby affording very material support.

"Members and their clerks declare they are worked to death. Small fortunes are amassed by jobbers in a week, although the dealers bewail that prices are so close nowadays that their former profits of 1905 have shrunk to sixty-fourths of what they were in that year of famed, if notorious, memory. Yet money can be lost quickly, even now. A dealer, making a shilling price to a broker in a couple of thousand shares in which there is a very free market, lost £400 over the transaction, the price moving against him before he had time to undo the bargain."

Coal Mining in Central West Virginia

A Brief Study of General Conditions, and Details of Operation at the Coalton Mine, Which Plant Is Typical of Mines of the Region

BY FLOYD W. PARSONS

During the recent midsummer session of the West Virginia Coal Mining Institute, held at Elkins, W. Va., the members present were afforded an opportunity to visit the Coalton plant of the Davis Colliery Company, situated on a branch of the Coal and Coke Railroad, a few miles south of Elkins. Although the general operation of this plant does not differ greatly from

the last portion of that State to undergo development. The presence of a thick seam of coal in the "Roaring creek" region was known before the Civil war. A block of coal from this district was exhibited at the Centennial in Philadelphia, in 1876. This last mentioned coal was hauled by wagons from a point located about two miles from the Coalton

While the presence of this field was known to some and rumored among others, the country was inaccessible until the completion of the Belington branch of the West Virginia Central Railroad. At that time, Senator Henry G. Davis and his associates owned the West Virginia Central. The first commercial mine in the roaring Creek region was at Junior.

GENERAL VIEW OF 1800-TON STEEL SLACK BIN, INCLINED STRUCTURE FOR ROBINS BELT CONVEYER, AND CHAIN-HOIST LEADING TO TIPPLE AT THE COALTON MINE

the general working of many other bituminous mines, the development here carried on is typical of conditions existing throughout this central district, so that a brief description of prevailing conditions and methods will not be out of place.

Because of the lack of adequate transportation and the general inaccessibility of the country, central West Virginia was

plant. The exact spot from which the block came, is, in fact, within a rod of the cabin in which General McClellan made his headquarters during the Rich Mountain battle. The coal exhibited at the Centennial was in two blocks, each 5 ft. thick, and many were incredulous that a seam of coal 10 ft thick existed in the Roaring Creek region.

This mine was started by H. G. Davis, Jr., being known as the Junior Coal Company, with 84 acres of coal land. The name, Junior Coal Company, was used until about six years ago, when the title was changed to the present one of Davis Colliery Company.

The Davis Colliery Company now owns more than 20,000 acres in the heart of

the Roaring Creek field, as well as being the operating company for the holdings of the Coal and Coke Railway, which amounts to 100,000 acres.

THE COAL AND COKE RAILROAD

The entire line of the Coal and Coke Railroad was completed and put in operation June 30, 1907. The road extends from Charleston to Leiter, a distance of 166 miles; and from Belington to Mabie, W.

Chesapeake & Ohio railroad. The Eastern outlet is over the Western Maryland (formerly the West Virginia Central). Some coal is shipped to distant points over the Baltimore & Ohio Railway.

In this connection, a brief history of the Western Maryland Railroad may be of interest. This road was incorporated by special act of the General Assembly of Maryland, May 27, 1852, under the name of Baltimore, Carroll & Frederick Rail-

road, and about 30,400 acres on the lines of the Baltimore & Ohio Railroad. On these lands there are some 26 mining plants and more than 1000 coke ovens; also administration buildings, department stores and more than 600 dwellings. The Davis Coal & Coke Company is the operating and sales agent for the Western Maryland coal properties. The amount of the authorized capital stock of the Western Maryland Company is \$60,-

The Engineering & Mining Journal, June 26, 1909.

SHOWING LOCATION OF ELKINS AND THE ROARING CREEK COALFIELD WITH REFERENCE TO EASTERN, WESTERN AND NORTHERN MARKETS

Va., 17.7 miles. The company was incorporated May 14, 1902, under the laws of West Virginia, and on Aug. 11, 1903, purchased the Charleston, Clendennin and Sutton Railroad, extending from Charleston to Otter, W. Va., 63.6 miles. The accompanying map shows the connections of the Coal and Coke Railroad, and the general location of the Elkins and Roaring creek field, with reference to Eastern, Northern and Western markets.

In reaching the Western market, the coal mined by the Davis Colliery Company is generally shipped to Charleston and proceeds from there west over the

road Company, which name was changed to Western Maryland Railroad Company in March, 1853. In 1902 the company acquired control of the West Virginia Central and Pittsburgh Railroad Company, operating railroads and extensive coal properties in West Virginia.

The West Virginia Central retains the ownership of all its coal properties and mining operations, but its entire capital stock is owned by the Western Maryland Railroad Company. This latter company, therefore, owns or controls about 135,000 acres of coal land, 107,000 acres of which are located on the lines of its West Vir-

ginia division, and about 30,400 acres on the lines of the Baltimore & Ohio Railroad. The preferred stock has been canceled.

CHARACTER OF THE COAL

The coal seam that is being generally developed in the Roaring Creek region, is known as the Lower Kittanning. According to Dr. I. C. White, of the West Virginia Geological Survey, there is little doubt that this seam is identical with the Lower Kittanning bed of the Pennsylvania section. The coal mined at Coalton is typical of that produced in other parts of the district. An average analysis of a number of samples shows the following:

Moisture	0.70
Volatile matter	29.30
Fixed carbon	64.19
Ash	8.81
Total	100.00
Sulphur	1.48
Phosphorus	0.032
B. t. u.	13,850

An average analysis of the coke made at the Coalton ovens, after burning 48 hours, shows:

Moisture	0.11
Volatile matter	0.82
Fixed carbon	83.44
Ash	15.63
Total	100.00
Sulphur	1.13
Phosphorus	0.038

A. P. Brady, of the West Virginia Geological Survey, reports the following structure for the Lower Kittanning coal near Coalton:

States, it would be considered an unusually valuable fuel; however, having to compete with such coals as those produced in the New River and Pocahontas fields, the operators who mine the Kittanning and Freeport seams in central West Virginia have a task that is not easy. Coal washeries are not as generally used in northern and central West Virginia as the nature of the coal here mined justifies. Two causes are responsible for this condition: First, the fuel produced answers very well, without washing, for the specific purposes to which it is put; second, there is an excessive productive capacity causing fierce competition which has placed the industry on a basis where only unavoidable expenditures are possible.

Conditions that have existed in south-

any preparation, such as washing and picking, but also has caused operators to mine their coal in the quickest and most reckless manner.

The severe depression in business that we have just passed through has taught a lesson that will not be forgotten immediately, and it is to be hoped that one result will be a better organized coal industry, with prices raised to a basis that will net operators a fair return on their investment, thus permitting the adoption of sensible and efficient mining methods, and making possible the introduction of such safety precautions as have been proved of practical benefit.

West Virginia, with a productive coal area of nearly 16,000 sq.m., and an estimated coal supply of more than 60,000,-

Coal	1	6		

The butts run south 80 deg. east; faces, south to deg. west, and the greatest rise of the seam in this district is south 30 deg. east.

PRODUCTION OF A CLEAN COAL

The great problem at the Coalton mine as well as at other plants in central West Virginia, is to produce a fuel having a small ash content. Thousands of dollars have been spent in experimenting with this end in view. This does not mean that the coal here mined is inferior in quality; on the other hand, if the coal here developed were located in certain Western

ern West Virginia are largely responsible for the present depressed state of the coal trade and its slow recovery. In this latter district a quality of coal unsurpassed anywhere in the world lies practically at tippie height, and is mined at a minimum cost. However, from the very beginning, the operators in southern West Virginia have been practically unorganized and have fought bitterly for the business of all accessible markets. The coveted trade has been practically controlled by the large consolidated interests in older fields, and the aggression of the small independent operators in southern West Virginia has been hotly contested. As a consequence, while wages and the price of commodities in general have advanced during a period of years, the price of coal has either remained stationary, or been held at a level that not only prevents

600,000 tons receives a return in net profit that is ridiculously small when compared with the value of her rich heritage. Large coal companies in this State have recently made long contracts to deliver coal at their mines for 60c. per ton. With an actual labor cost approximating 45c. per ton, it is not hard to figure where the coal operator is going to get off.

Mining men in the United States are now evincing an interest in the methods used abroad and the equipment of European mines, and some have gone so far as to suggest that American mines could be made to compare favorably with those in Europe, however, such plans cannot be consummated here while present conditions exist. Tiled floors and stained-glass windows in the power house of a Continental colliery are possible with coal at \$2.20 per ton, but not possible in the

United States with our product selling at the mines for 70 or 80c. per ton.

The Coalton plant of the Davis Colliery Company is one of the best equipped properties in central West Virginia. This mine was purchased by the present owners from other interests who knew the property as the Wormelsdorf plant. The early owners did not develop the mine in a systematic manner, and, as a consequence, the left side of the underground workings was subjected to a number of squeezes which resulted in the loss of considerable coal.

SURFACE EQUIPMENT AT COALTON

The Davis Company has provided 102 houses for its Coalton employees. These houses are of the five- and six-room variety; 78 are ceiled, and 24 plastered.

stall is a bucket-shaped metal vessel having a horizontal-slide bottom. The bottom of each of the feed buckets is connected to a cable running on pulleys in such a way that the slide bottom remains open when no mechanical force is exerted. The stableman can close all of the boxes by pulling down on the cable which runs over a pulley and hangs down alongside a post. A ring is attached to the end of the cable, and when the latter is pulled down a sufficient distance to close the bottoms of the feed buckets, a long steel pin is extended through the ring on the cable, and the end of the pin, which is pointed and straight, is placed underneath a nail driven in the side of the post.

Directly alongside this same post and on a shelf at about the same elevation as

the moment the alarm rings, all of the mules quickly step back, knowing that the feed is going to drop from above.

THE COKE OVENS

At the Coalton plant there are 200 ovens, arranged in two blocks of 100 each. These ovens are of the ordinary beehive type, with the floor in the ovens falling to the front on a slope of 7 in. in 12 ft. The bottoms of the ovens formerly were built with an incline to the front of 5 in., but this slope was found insufficient to insure a quick drainage of the water used for cooling the coke. The net tonnage of each oven is about 3.8, while the coke output averages 73 per cent. Everything that goes through a 1½-in. screen is crushed by a Williams hammer crusher, and is used in the manufacture of coke.

GENERAL VIEW OF COKE OVENS AT THE COALTON MINE, ALSO SHOWING THE STEEL SLACK BIN, TIPPLE AND POWER HOUSE DURING CONSTRUCTION

A few of the plastered houses are built of brick. The rents vary from \$6 for a five-room wooden-ceiled house to \$9 for a six-room plastered brick house. The general design of these buildings may be noted in the accompanying illustration. The company's department store is of the usual type common to coal mines. Scrip is issued and is accepted as cash for all purchases.

A UNIQUE AND SIMPLE ARRANGEMENT

The mine barn is a substantial and commodious structure, far better than the average mine stable. The most unique feature in connection with the barn is a simple arrangement for mechanical feeding. The grain and hay are kept in bins on the second floor; on this upper floor and directly over the feed box of each

the nail which catches the pin and holds down the cable, an ordinary alarm clock is placed. The other end of the pin, that holds down the cable, is fastened to the key that is used to wind the alarm on the back of the clock. This alarm can be set for any specified time, so that at the desired moment the alarm starts to ring, the key on the back of the clock revolves, the pin is pulled away from contact with the nail in the post, thus releasing the cable and allowing the bottoms of the feed buckets to slide open, dropping the grain into the manger in the stall below. This simple arrangement enables the stableman to set his alarm for any hour, then fill the feed buckets and leave the stable, feeling sure that at the proper time the feed will be dropped to the animals in the stalls below. It is stated that

The Williams crusher has given excellent service. This machine takes anything up to 1½ in. in diameter, and although small pieces of steel go through almost every day, the crusher has not been disarranged or broken.

THE STEEL BIN

The most interesting feature at the Coalton plant is the 1800-ton steel bin that was manufactured and installed by the Fairmont Mining Machinery Company. This bin is made entirely of steel and is shown in the accompanying illustration. The bin feeds into a 7-ton electric larry which supplies the ovens located nearby.

The underground development carried on by the Davis Colliery Company, at this mine, has been carefully planned and well executed, as is shown by the accompany-

ing mine map. All entries and rooms are driven on centers, so that an effort has been made to leave uniform pillars, and thus prevent a loss of coal through the occurrence of any unnecessary squeezes.

The average thickness of the seam is

and no machines used. It is probable that in the near future experiments will be made to see whether machines cannot be successfully introduced. Electric underground haulage is used and two General Electric, 7½-ton locomotives and one 13-

gerous but it is common in many West Virginia coal mines. No serious accidents have happened from shock.

MINING METHODS

The underground problems that have so far been encountered are simple in the extreme. The mine is fairly damp and non-gaseous, so that the constant problem of eliminating dust and gas explosions is not the uppermost question. Notwithstanding the fact, however, that such safety prevails, the ventilation is carefully conducted and is said to be ample at all times. A 20-ft. Robinson fan provides the air circulation at present. This ventilator is 8 ft. wide, and is steam-driven, running at 60 r.p.m. This same fan was formerly driven at 100 r.p.m., and delivered no more air at the face than it does at present. The improved conditions that now exist resulted from the management having had all inside stoppings carefully looked after and repaired. These stoppings are now built 5 to 8 in. thick, and are made of a material, composed of 20 per cent. cement and 80 per cent. coke cinders.

The dip of the seam is such that all drainage is natural and is accomplished by a network of ditches. The rooms are driven on about 50-ft. centers, and are 20 to 28 ft. wide. The entries are protected by small barrier pillars; these latter are not as large as is usually the case in a coal of this character and they are not kept intact, as is shown on the accompanying map.

The prevailing method is to take the pillars back immediately, drawing them on an angle of about 45 deg., and the general scheme at Coalton is to secure as high a percentage of extraction as is possible on the advance, rather than to develop the mine and extract the pillars retreating. Although in a majority of cases this plan is ill-advised and results in a final loss of coal, conditions here are somewhat different, and it must be remembered that only about two-thirds of the seam is mined, which provides a coal roof of considerable strength.

PREPARATION OF THE COAL

After the coal is mined and hauled to the room partings by mules, it is then made up into trips and hauled by motors to the foot of the slope near the mouth of the mine. The cars are here dropped, one by one, to a swag at the bottom of the incline, where each car is engaged by a dog on the chain-haul which hoists the coal to the tippie floor above; from here each car runs by gravity to the Phillips cross-over dump where the coal is shot onto the screens, and the empty car runs by gravity through a spring-latch switch and is lowered back into the mine.

The mechanical hoist that raises the cars from the mine to the tippie was also built by the Fairmont Mining Machinery Company, and has given good service.

The dogs on the cham are arranged at 16-ft. centers; the car hoist is 70 ft. long, with a 21-ft. lift. The hoist is driven by a General Electric 30-h.p. motor.

After the coal is dumped onto the screen, all sizes greater than $1\frac{1}{4}$ in. go over other screens and the coal is further separated into nut, lump, etc., or the entire product is shot into the railroad cars without any additional screening, and is then sold as screened run-of-mine. As before stated, the under-size (all under $1\frac{1}{4}$ in.) goes to the Williams crusher and is pulverized. This fine product is then elevated on a belt conveyor (the housing and incline of which are shown in the illustration) to the top of the 1800-ton steel slack bin. This belt conveyor carries the slack satisfactorily, but is too steep to carry nut coal. The belt conveyor here used is of the Robins type, 360 ft. long, with a lift of about 130 ft. A 60-h.p. General Electric motor drives this conveyor.

COAL TIPPIE AT THE HARDING MINE OF THE DAVIS COLLIERY COMPANY.
A STYLE OF DESIGN COMMON TO WEST VIRGINIA

The design and erection of the steel tippie at the Coalton mine was also executed by the Fairmont Mining Machinery Company. The arrangement of the shaker screens does not differ materially from the general run of tippie installations. The screens are driven by a 30-h.p. General Electric motor.

The miners at this and other plants in the district are principally foreigners, and, as in other West Virginia fields, they are unorganized. Wages in Central West Virginia do not differ materially from those paid in other parts of the State. A miner receives 80c. for a 2-ton car, which is practically the same as that paid in the Fairmont region.

All members of the West Virginia Coal Mining Institute who visited the Coalton plant are greatly indebted to C. S. Robb, general manager of the Davis Colliery Company; J. F. Healy, general superintendent, and F. C. Cornet, chief engineer.

There are few engineers at present who contend that direct-current is as safe as three-phase current in gassy mines.

Aluminum in Japan

W. T. Preston, Canadian trade commissioner in Japan, reports to the Canadian Department of Trade and Commerce that though an aluminum factory was started in Osaka recently, practically all the aluminum used in Japan comes from foreign countries. The importation of aluminum has increased from 83,879 lb., valued at 36,703 yen in 1901 to 2,445,403 lb., valued at 1,803,217 yen in 1907. Ten years ago the demand for this metal was quite limited, the sudden increase being caused by the adoption of military equipment made from aluminum, by the army authorities seven years ago, followed by its use for cooking utensils. If the cost of material continues to be as moderate as at present the prospects are favorable for a great expansion in the manufacture. An active demand for aluminum ware exists in China, and large orders have

blocks, etc., for the fiscal year 1907, amounted to 4,981,000 lb., valued at \$1,048,533. Mr. Preston points out that the largest customers for the Canadian output—Belgium and Great Britain—are extensive sellers to Japan, and that there is a wide difference between the prices at which Canada sold and those which Japan paid. The export price from Canada in 1907 was \$18.79 per 100 lb. The cost of aluminum imported into Japan the same year was \$39.57 per 100 lb., the difference of \$15.78 per 100 lb. being too large to be swallowed up in freight and other importation charges.

The Namaqua Copper Company

The report of this South African company for 1908 states that operations were conducted without profit to the shareholders owing to the low price of copper ruling throughout the year. In previous years the company has paid good dividends, having distributed as much as 40 per cent. on the capital in 1899.

During 1908 there were 46,200 tons of ore from the mines and dumps dealt with, producing 2335 tons of fine copper, against 42,400 tons of ore in 1907 producing 2432 tons fine copper. The reserves of ore in the mines and at surface are estimated at 115,204 tons, carrying 7985 tons of fine copper. There is also a reserve of slimes and tailings suitable for retreatment estimated at 84,729 tons, value not stated.

The two furnaces at the smelting works were kept in regular operation except during November and December, when the wreck of a coke ship caused a shortage of coke and the furnaces had to be shut down.

All fines from the ore, as well as concentrates, slimes and a portion of old jig tailings, are now briquetted and a much larger portion of this class of material has been charged in this form, whereby a reduction in loss by dust is secured.

The Elmore vacuum oil plant was in operation up to June 27, when it was shut down, the results obtained not warranting the running of the plant under the conditions then prevailing. The quantities treated by this process were 1639 tons of 2.81 per cent. copper, which produced 83.5 tons of concentrates containing 31.71 per cent. The extraction, therefore, was slightly over 57 per cent.

In the Twefontein mine No. 1 shaft was deepened 233 ft. to a total depth of 1140 ft. No. 2 shaft was deepened 114 ft. to a total depth of 750 ft., with more encouraging results than in No. 1. Development work and stoping were also carried on in the Wheal Julia mine. Work in the new Prospect mine was closed down at the end of March, as reduced price of copper made it inadvisable to continue working on the narrow lode and low-grade ore that were met

(Canadian export of aluminum in bars,

Colliery Notes

One volume of firedamp is sufficient to reduce the whole of the oxygen present in nine volumes of air to carbon dioxide and water, and less than 6 per cent. will propagate a flame.

Power gas is produced by passing quantities of air and steam through incandescent fuel. This gas consists largely of carbon monoxide and is used for power and heating purposes.

It should be remembered that it requires no more than 3 grams of coal dust per cubic foot of air to give the requisite quantity of carbon to reduce the whole of the oxygen present to carbon monoxide, or a proportion by weight of 1 of dust to 13 of air.

Coke that is to be used for the manufacture of iron or for other metallurgical purposes, should be firm, tough and light, and should have not more than 1 per cent. of sulphur. For blast-furnace purposes, dense coke is not so good as those varieties possessing large cell structure and hard cell walls.

At one colliery where it was decided to experiment with water, as a means for preventing dust explosions, a large spray was thrown right across the roadway. The officials expected that this spray would dampen the air sufficiently to insure the dust being laid for a considerable distance. They were surprised, however, to find that the effect of the spraying was lost after the air had traveled 1500 feet.

Coal gas, such as is manufactured and used in various towns and cities for lighting purposes, is produced by the distillation of coal out of contact with the air. This gas is composed of the following elements or compounds, in about the proportion named: Carburetted hydrogen, 40 per cent.; hydrogen, 30 to 35 per cent.; carbon monoxide, 6 to 8 per cent.; carbon dioxide, 3 to 4 per cent.; oxygen, 3 to 5 per cent.; nitrogen, 7 to 8 per cent.

It was formerly the general opinion that the dust lifted by the ventilation and lodged on the bars and other ledges in a mine was the most readily combustible and dangerous; however, more recent observations have shown by analysis that the dust lodged on the higher ledges, near the roof, generally contains a much greater proportion of ash, as compared with that either from the screens or from the roadways, and less volatile combustible matter.

According to a bulletin, recently issued by the United States Office of Public Roads, the application of calcium-chloride solution to a macadamized road near Washington resulted satisfactorily in laying the dust. Of the commercial salt, 600 lb. were used, dissolved in water in the proportion of 1 lb. to 1 gal. of water. The solution was applied five times during the summer over 1582 sq.yd., at a total cost

for the season of about 2c. per sq.yd. The bulletin states that although much traversed by motor cars, the treated roadway was kept free from dust and became smooth and compact.

It is estimated that a cubic foot of certain varieties of bituminous coal yields: 7 cu.ft. of gas (occluded); 350 cu.ft. of coal gas (on distillation); 54 lb. of coke. The total volatile matter in a cubic foot of coal is estimated to weigh 26 lb.; in this latter estimate, the coal gas is figured at 10 lb. If steam and air are passed over the 54 lb. of coke in a producer-gas retort, the result is to generate 4122 cu.ft. of producer gas. It is further estimated that one ton of coke, 90 per cent. carbon, yields 171,000 cu.ft. of producer gas. Acetylene gas is made by fusing the coke with lime in an electric furnace. By this means calcium carbide (CaC₂) is formed.

There has been considerable discussion concerning the relative merits of salt, as compared with calcium chloride for the treatment of dust on the roadways and chambers of coal mines. Salt of itself has not the power of attracting moisture, but owes what little power it does possess to a small amount of impurity which it contains in the form of magnesium chloride; what little moisture salt does attract is again yielded up at a very few degrees rise in temperature above the normal. On the other hand, calcium chloride retains its moisture at temperatures considerably above 350 deg. F., as this temperature is much exceeded in its manufacture. It holds moisture most tenaciously, even at the above temperature.

Coal is a compound, but a very complicated one; in fact, each variety of coal is really a different compound. Every variety of coal should be regarded as the combination of a number of elements and compounds existing in different proportions, some of them being present always, and some only occasionally. When coal burns, most of the elements combine to form a compound with the oxygen in the air and are given off in gaseous form. Those which do not combine with oxygen, or which form a solid compound, remain behind as ash. In the combustion of coal the oxygen of the air alone enters into combination with it, and so far as is known, the nitrogen of the air has little or no effect on the composition of the products of combustion.

It has already been stated in these notes that calcium chloride (especially when used in the form of a finely ground powder) does not affect the roof of coal mines in such a deleterious manner as does water. It may be further stated in this connection that the action of calcium-chloride liquor upon iron and steel is not one-third so vigorous as the rusting action of plain water. Henry Hall, of England, who is an authority on this subject, recently stated that iron exposed alternately

to dampness and air rusts far more quickly than iron, exposed to calcium-chloride liquor and air alternately. He says: "This is confirmed by the fact that the bogie rails in the calcium-chloride manufactory, where they are saturated with the article, are as good as new; but in one or two places where water has dropped on them, they are rusting badly and show signs of great wear."

In some mines where an explosion has been largely due to dry coal dust, the investigators have been puzzled because there were no evidences of coked dust on props and on the sides of the entries. Professor Galloway recently stated that this absence of coked-coal dust in certain parts of the workings through which the explosion must necessarily have traveled, was due to the impure nature of the coal dust contained in them; that the dust contained a sufficient proportion of shale-dust to prevent it from forming a coherent coke, or adhering to the timbers and other objects against which it was thrown in a molten condition during the passage of the explosion. In discussing this same problem, Victor Watteyne, inspector general of mines in Belgium, suggested that this absence of coked-coal dust was due to the much higher velocity of the explosion in those parts of the workings, rather than to the impurity of the dust.

In drawing conclusions as to the cause and action of coal mine explosions, the average investigator in this country often ignores well known principles that have been proved beyond doubt. Two European authorities on coal-mine explosions, after carrying on examinations at several collieries where disastrous explosions had occurred, gave the following closely-reasoned analysis of the phenomena observed:

1. In several instances it was found that there was an entire absence of any evidence of the presence of firedamp immediately prior to the occurrence.
2. That the parts of the mine, such as main intake, where it is hardly possible for gas to lodge, are often the scene of the greatest destruction.
3. That the blast sweeps along in a particular direction and leaves other roadways unaffected, whereas the sudden explosion of an accumulation of firedamp and air might be expected to follow the line of least resistance.
4. That the last working-places of a district, and the returns, which, as is well known, are liable to be contaminated with firedamp, hardly ever appear to have played any part in the explosion.
5. That at or near the point of initiation of an explosion, violent effects are seldom found, and everything suggests a gradual increase of force, fed by some agent as the blast travels along and rapidly develops a tornado rushing to the extreme limits of the workings.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT MCKEAN, Sec'y.
505 Pearl St., New York.
London Office: 6 Bonnerie Street, London, E. C., Eng.
Cable Address "ENGINJOURN, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for May, 1909, was 52,000 copies.

June 5.....	11,000
June 12.....	9,500
June 19.....	9,500
June 26.....	9,500

None sent free regularly, no back numbers. Figures are live, not circulation.

The Consumption of Lead in 1908

The matter of estimating the consumption of lead in the United States in 1908 is one that we approach with some diffidence owing to the absence of complete, or even fairly complete, data as to the stock in first hands at the beginning and end of the year. In this respect the lead industry is highly deficient as compared with copper and spelter. The reason is obvious. The marketing of lead is so largely in the hands of a single company that it is disinclined to communicate information as to its accumulation of metal even at a late date.

We estimated the stock on Dec. 31, 1907, at 50,000 tons, on the basis of partial reports and some other information. Adding stock, production of refined lead, and imports of refined, and deducting stock and exports, the deliveries in 1907 were computed at 330,738 tons, and the latter figure was taken to be also the consumption. We had reports from domestic manufacturers accounting for 294,029 tons. The same manufacturers in 1908 reported 257,759 tons, indicating a consumption of 87½ per cent. of the amount in 1907. If, then, the total consumption in 1907 was 330,738 tons, the total in 1908 was probably about 290,000 tons. This would imply a total accumulation of about 94,000 tons.

The refiners probably had no such stock as 94,000 tons, sold and unsold, in their hands at the end of 1908. However, their aggregate accumulation was clearly larger than what has been commonly believed, and we are inclined to estimate it at 75,000 tons, leaving about 20,000 tons to be accounted for in second hands, including manufacturers, some of whom are known to have been in an overbought condition during the year. The statistical position of lead was consequently analogous to that of spelter, which we have previously described. We have summarized the data in the following tables:

DELIVERY OF LEAD.

(In Tons of 2000 Lb.)

	1907.	1908.
Production desilverized	289,349	260,612
Production Missouri lead	127,133	131,117
Production antimonial lead	9,614	113,109
Imports of refined lead	9,277	2,750
Stock, domestic, Jan. 1	4,000	50,000
Foreign in bond, Jan. 1	5,691	12,897
Total supply.	445,114	479,524
Re-exports of foreign lead	51,424	76,328
Exports of domestic lead	145	nil
Stock, domestic, Dec. 31	50,000	75,000
Foreign in bond, Dec. 31	12,807	18,462
	114,376	169,790
Delivered	330,738	309,734

CONSUMPTION OF LEAD.

(In Tons of 2000 Lb.)

Purpose.	1907.	1908.
White lead and oxides	115,000	117,500
Pipe	41,000	33,800
Sheet	21,500	16,400
Shot	28,000	31,800
Other purposes	125,238	90,700
Totals.	330,738	290,000

PERCENTAGES OF CONSUMPTION.

	1917.	1908.
White lead and oxides	34.8%	40.5%
Pipe	12.4	11.6
Sheet	6.5	5.7
Shot	8.5	10.9
Other purposes	37.9	31.3
Totals....	100.0	100.0

The above figures are deficient through their omission to take into account the production of lead from scrap and junk. In 1907, according to the U. S. Geological Survey, this amounted to 9990 tons. In 1908, according to our figures, the amount was 14,323 tons. Probably there was no actual increase, the larger figure for 1908 being attributable to a more complete statistical enumeration. The actual consumption was by so much greater in each year.

Terminating the Life of a Company with the Mine

It is a common practice among English mining companies—though not as usual in this country—to accumulate a surplus, as the mine approaches exhaustion, for the purpose of purchasing a new property. Sometimes the property acquired is situated in the vicinity or in the same district as the mine which is at the end of its life, but several instances could be given of companies that have gone further afield and have embarked in new mining ventures in other parts of the world. When the new property is situated in the same district, there is a good deal to be said for the adoption of this policy. The experience and knowledge that have been acquired should go far to make the selection of new ground a wise one, and there is the advantage of having an organized staff for the new undertaking, fully acquainted with the local conditions.

When, however, a mining company looks for a new mine outside its own district, it is not so easy to defend this policy. Those who invest their money in a mine do so in the expectation that the mine will be worked to the best advantage and that the profits will be distributed to them and not risked in new ventures. It may be assumed that in buy-

ing shares in any mine for investment they have done so because they believe in that particular property, or in that district, or perhaps in the mineral that is being won. If they had known that their investment were to be changed at the will of the directors and that the profits earned were not to be fully distributed, but were to be re-invested in some other mine of which they had no knowledge and in which they take no special interest, it is probable that they would not have invested at all. This, of course applies to persons who buy a stock for investment, not to those who buy because they hope to sell at an advance, and who look at the stock exchange, not the mine.

The powers of directors are, of course, regulated by the articles of association and shareholders could, if they wished, prevent their directors from speculating in this way. But, as a rule, the average shareholder knows nothing about the articles of association, which are usually drawn up in such a way as to give the directors power to acquire fresh interests without consulting the shareholders. If the sanction of the majority of the shareholders is obtained at a general meeting, nothing more can be said, but without that sanction it does not seem justifiable for directors, although protected by articles of association, to take upon themselves the responsibility of withholding the profits of the shareholders and investing them in some new undertaking. The adoption of this policy is also open to the objection that the directors and other officials are interested in the continuation of the company and, therefore, cannot help being biased in favor of the acquisition of new ground.

A recent instance of a company that is embarking in fresh fields is the Oroya-Brownhill of Western Australia. According to the report for the year 1908, the mines of this company are approaching exhaustion. Every effort appears to have been made to acquire extensions in the vicinity of the present mines and it is hoped in this way to continue profitable operations for some years to come. But to safeguard the existence of the company, the policy of acquiring a new mine, in whatever quarter of the globe it might be found, has been adopted. After examining a number of mines in different parts of the world the directors have acquired La Leonesa mine in Nica-

ragua, as well as an option on the Babilonia mine in La Libertad district in the same country. Both of these properties have been favorably reported on by C. S. Herzog. In this case it is important to point out—having regard to what has been said above—that the policy of going into fresh fields was explained to the shareholders at the annual general meeting held a year ago and met with formal acceptance. Against their particular action, of course, nothing is to be said.

From the information given by the chairman at the general meeting, held in London recently, it appears that it is no easy matter to find a promising property at a reasonable price. The directors have perused and considered the reports on 60 properties in the Malay States, on 65 in Western Australia, on 22 in Burma and on 125 in other countries. H. C. Hoover, one of the directors, also gave some interesting information as to the difficulty of finding a good mine; which, however, was not due to any scarcity of mines for sale in London. No less than 680 mining properties were offered; of these about 400 were turned down at once, 150 were rejected after some negotiation, 130 were looked into on the ground to some extent, 20 had been exhaustively examined, one had been purchased and three taken under working options. Such statistics as these are creditable to the managers of the company, since they show that care has been exercised in selecting a property. They also indicate the risk that a company runs, which is not advised by cautious and competent engineers.

Mining Stocks as Investments

There has been much interest of late over the listing of some of the stock of the Steel Corporation on the Paris Bourse. The purpose of this listing is, of course, to effect a distribution of this security among French investors, whose accumulations are very attractive to financiers. We are not going to take up the special matter of the listing of steel, but refer to it in order to point out the favorable attitude of French investors, whose caution is well known, toward mining and industrial enterprises. The Bourse at Paris differs from the stock exchanges at New York and London by being to a large extent a national affair, over which the min-

ister of finance has much control. The favorite security upon the Bourse for a long time has been a copper-mining company, the Rio Tinto. After this, the interest of French investors is now centering in the stocks of the Rand gold-mining companies, in the distribution of which great houses are engaged.

The prominent position of these mining stocks in Paris is widely different from that of similar securities in the United States, where trading in them is largely relegated to the unregulated "Curb market," and even the best are regarded askance by the banks. Yet there are very few forms of property that are so secure as the shares in mining companies that have 10 to 20 years' supply of ore developed ahead. The purchase of a share in such an ore reserve is more analogous to the purchase of real estate than anything else. It is property that actually exists. Unfortunately the number of mining companies that can make such showing is limited.

The thing that has brought most discredit upon mining investments is the impressive vamping of the "get-rich-quick" men. How best to curb them has long been the attention of many students. The most practicable plan was suggested by Governor Hughes' commission on speculation, which said: "A large part of the discredit in the public mind attaching to 'Wall Street' is due to frauds perpetrated on the small investor throughout the country in the sale of worthless securities by means of alluring circulars and advertisements in the newspapers. To the success of such swindling enterprises a portion of the press contributes. Papers which honestly try to distinguish between swindling advertisements and others may not in every instance succeed in doing so; but readiness to accept advertisements which are obviously traps for the unwary is evidence of a moral delinquency which should draw out the severest public condemnation. So far as the press in the large cities is concerned, the correction of the evil lies, in some measure, in the hands of the reputable bankers and brokers who, by refusing their advertising patronage to newspapers notoriously guilty in this respect, could compel them to mend their ways and at the same time prevent fraudulent schemes from deriving an appearance of merit by association with reputable names." This is precisely what the Journal has previously urged.

The Ooregum Gold Mine

SPECIAL CORRESPONDENCE

The report of the Ooregum company, operating in the Kolar goldfield in India, for the year 1908 shows a record output of gold, the value being £329,317, derived from 121,886 tons, equal to a value per ton of 5s. The mine has now been a gold producer for 20 years, the total gold won amounting in value to £4,866,656. Judging from the favorable report of the directors recently issued, the mine promises to continue its prosperous career, the outlook for the present year being more encouraging than it has been for some years past.

The main vertical shaft, Bullen's shaft, has been sunk to a vertical depth of 3210 ft. The intersection in this shaft of the principal reef, assaying over 1 oz. gold to the ton at 3147 ft. from surface, is an important feature, as it proves the existence of good ore in this reef 200 ft. below the present bottom level of the mine. The ore reserves, estimated at 154,281 tons, for which no value is given, are none too large for a mine of this size, being equivalent to little more than a year's run of the present mill.

Besides the ore reserves in the mine, there is an asset of 80,000 tons of tailings, slimes and concentrates available for treatment. The working costs of the past year amounted to £165,974, classified as follows:

	£	Per Ton Million
Administration.....	55,768	\$0.240
Mining cost.....	112,036	4.416
Milling cost.....	13,462	0.528
Tailings cyanide treatment..	8,804	0.336
General.....	25,904	1.008
Total.....	£165,974	\$6.528

As is customary with the Indian mines under the control of John Taylor & Sons the whole of the capital expenditure for the year is charged against profits. Including amounts for depreciation of buildings and machinery the sum deducted from profits in this way was £53,465. In spite of this large deduction it was possible to pay dividends during the year 1908 at the rate of 3½ per cent. on the preference shares and 2½ per cent. on the ordinary shares; dividends which the shareholders will no doubt consider satisfactory, although the rate has been exceeded in former years.

The mine superintendent's report contains a large amount of detail as regards the underground development, most of which, however, must be of interest and intelligible to few. The report would be improved if the working costs were shown on a tonnage basis and if the ton used were that of 2000 lb., as recommended by the Institution of Mining and Metallurgy, instead of 2240 lb. The change from the long ton to the short ton might make some confusion in the statistics of the

mine, but this difficulty might be overcome by having the figures worked out side by side on both standards. The metallurgical department seems a little behind the times, the plant for treating slimes being still in an experimental stage. The sands plant treated 108,869 tons of an average assay of 2 dwt. 19 grains; the recovery was 1 dwt. 21.5 grains or 68.5 per cent.

Although there was only one case of plague during the year the labor supply was interfered with by a mysterious sickness, much resembling cholera, from which there were 44 deaths. The disappearance of plague is attributed to the destruction of rats and mice, of which 17,328 were destroyed on the company's property.

The Distribution of Transvaal Gold

SPECIAL CORRESPONDENCE

In the JOURNAL of May 15 there was a notice of a paper by Dr. T. Kirke Rose, written for the Chemical, Metallurgical and Mining Society of South Africa, in which the distribution of the gold produced on the Rand was discussed. In the April number of that Society's JOURNAL, Dr. Rose publishes some correction in the figures originally given. His figures for the imports of gold bullion into the United Kingdom did not account for the gold contained in imported ore, which for the five years 1903 to 1907 amounted in value to £4,137,334. The gold is extracted and converted into bullion in England, and must be counted as part of the available supplies. The revised figures for the total amount of bullion (apart from coin, old material, imported gold-leaf, imported watch cases, etc.) used in the industrial arts in the United Kingdom in the years 1903-1907 are £8,400,000 or £1,680,000 per annum. Hence about 5.4 per cent. of the Rand gold was used in the industries in these years and 30 per cent. for coinage, instead of 4.2 and 31.3 per cent. as given in the original paper.

Copper in Russia

SPECIAL CORRESPONDENCE

A report from the French Ministry at St. Petersburg, published in the *Moniteur Officiel du Commerce* in Paris, gives a statement of copper production in Russia. The output by districts for two years past is given below, the Russian measures being reduced to pounds:

	1907.	1908.	Changes.
Ural.....	16,829,033	18,863,715	I. 2,334,682
Caucasus.....	11,194,661	10,698,393	D. 496,268
Altai.....	101,072	190,917	I. 89,845
Siberia.....	2,968,969	5,408,305	I. 3,929,336
From chemical works.....	2,365,438	1,071,472	D. 383,966
Total.....	32,572,273	37,192,802	I. 4,660,529

Production is lessening considerably in

the Ural owing to the temporary closing of the Demidov works and the competition of new producers elsewhere. It has also gone down in the Caucasus, chiefly at the Siemens works, where the output in 1908 was only 3,087,124 lb., against 3,924,321 lb. in 1907. The same may be said of the last group, including copper from works operating by chemical process and of the refineries.

Production in Siberia and the Kirghiz district showed a large increase. The reports of the two principal companies show the following output, in pounds:

	1907.	1908.	Changes.
Yenisei.....	523,154	1,857,019	I. 1,333,865
Spassky.....	1,864,915	3,561,295	I. 1,486,380

In 1907 the Yenisei company worked only for six months. In 1908 the company worked the full year, the average production being 214,127 lb. per month. The Spassky company in 1908 averaged 479,296 lb. per month, or 262,914 lb. more than in the previous year.

In the Altai work was carried on for seven months in 1907, but for only two months in 1908. Nevertheless there was an increase last year. It may be noted that these mines are only in the development stage, and that a great growth in production may be expected.

The consumption of copper in Russia is estimated as follows, for two years past, in pounds:

	1907.	1908.	Changes.
Production.....	32,572,273	37,192,802	I. 4,660,529
Imports.....	10,829,100	10,865,197	I. 36,097
Total supply..	43,401,373	47,997,999	I. 4,596,626
Exports.....	3,934,573	252,679	D. 3,681,894
Consumption..	39,466,800	47,745,320	I. 8,278,520

The production in 1908 showed a gain of 14 per cent. The gain in the approximate consumption was 21 per cent., the exports having fallen to a very low figure.

A Transaction in Radium

According to the New York *Sun*, the largest order for radium ever given has just been placed jointly by Lord Iveagh and Sir Ernest Cassel, who will donate it to the Radium Institute for the foundation of which they have provided the funds. The quantity ordered is 7½ grams—about ¼ oz. avoirdupois—and the price is \$150,000. The largest amount previously bought at one time was 1 gram. The order was given to the British Metalliferous Mines Company, which will obtain it from the Cornish pitchblende deposits under the superintendence of Prof. Giesel, the company's chief chemist.

Metallic chromium is now a commercial article (*Brass World*, May, 1909) and can readily be obtained of high purity and at a reasonable price. As far as known, it has not yet become a constituent of the non-ferrous alloys, although it has long been used in making very hard and tough steels.

The Kilker Matte Tapping Car

By F. T. HAVARD*

The Kilker matte-tapping car is an example of one of those simple machines which affect such an appreciable saving in the working costs of a smelting plant, that we must wonder at the tardy development and application of the idea in what we are pleased to call the rapid progress of modern metallurgical enterprise.

It has long been recognized that the method, adopted by most of our lead smelters, of tapping matte from the receiver or forehearth into the small matte pots of 300 or 400 lb. capacity, and subsequently breaking and transporting the matte cones to the railroad cars or hoists, was costly, clumsy and inefficient. But the most unpleasant feature lay in the periodic "run-aways" of matte from the receiver, which accompanied the use of the small pots, particularly if the matte fall was at all

and the smelting staff at East Helena into the type of the machines now used at Selby, East Helena and elsewhere, which combine strength and simplicity with thorough efficiency. In fact, Kilker's car embraces all the essentials required to insure its adoption as a standard vehicle for the tapping, molding and transport of matte in all the silver-lead and in many of the copper smelteries of the world.

One safeguard, however, is necessary in working with the car: the lead in the receiver must be kept below the level of the matte tap. Should it be allowed to run with the matte into the car, it will splash and be lost or burn the operators.

CONSTRUCTION OF THE CAR

In tapping matte into the Kilker car, it is usual to place the car in position on the rails on the short side of the receiver. A curved spout leads from the matte hole to the car. Instead of a curved spout alone such as the illustration shows, a small brick-lined cast-iron box on wheels

ance of the pans on the spider is the key to the successful manufacture and operation of the "merry-go-round." A wrought-iron yoke revolves around the pin and the top of the pan strikes against this when being dumped. The pan is held in position at an angle of about 60 deg., with the lug resting on the outside rim of the spider.

TAPPING OPERATIONS

The 10 pans hold between 3000 and 3300 lb. In East Helena two are in use at each furnace. The method of procedure is as follows: When the car is placed beside the receiver it is slowly set revolving and kept in motion during the tapping until the furnace man plugs the hole. It is at once hauled out toward the dump about 50 yd. by an electric locomotive, and uncoupled; it then runs by gravity to the track above the box cars. An empty "merry-go-round" from the previous tap stands on a side track ready to be hauled beside the receiver. After standing 30 minutes the matte contents are dumped

SECTIONAL ELEVATION OF KILKER CAR—CHAIN REPLACED BY YOKE IN LATER MODELS

The Engineering & Mining Journal, N.Y.

considerable, that is, above 23 or 24 per cent. of the charge.

It was on account of the vexatious delays in stopping the furnace and the disagreeable work of cleaning up the floor plates, which invariably resulted when the tapper failed to plug the matte hole, that a foreman in the American Smelting and Refining Company plant at East Helena, Mont., sought a safe and efficient method of coping with the task of tapping and transporting the matte. Mr Kilker conceived the idea of using a horizontal wheel as a carrier for a number of pans which should revolve and cast the matte in thin layers, one to every revolution, so that on the subsequent dumping of the pans the matte should fall to pieces of a suitable size for the sampling mill or the furnace.

This original idea has developed under the auspices of the able master mechanic

may be placed directly in front of the matte hole, and from this box a curved spout leads the matte to the car. The use of this curved spout enables the matte tapper to work with his bar or plug directly in front of the receiver without the danger of being burnt by the hot matte.

The car is known as the "merry-go-round," and the receiving box as the "baby carriage." The wrought-iron frame of the "merry-go-round" is made of I beams and mounted on roller-bearing cast-iron wheels. On the framework is an upright steel pin, on which revolves the spider that carries the pans. In the more recent machines the spider is a solid steel piece and 10 pans, every one an equal segment of the circle, sit in position on the spider. These pans are cast with a lug on the bottom in such a position that they are prevented from slipping on the car and from falling when the pans are dumped in the manner shown in the accompanying picture. In fact, the nice bal-

into the box car by raising the small end of the pans; three pans are tilted at a time against the wrought-iron stay bar and then knocked back into position. The "merry-go-round" and the stay bar are then revolved in opposite directions and three more pans are dumped until the matte is all unloaded. The whole operation takes only a few minutes. The pans are then "washed" with adobe clay and the car is ready for the next tap.

In one of the appended sketches no stay yoke is seen, but in its stead is shown a chain which was formerly used to keep the pans from swinging too far when being dumped. The life of the pans is good, particularly if care is taken to warm them all over before tapping into them. It is estimated that the use of the car has reduced the cost of working the matte by about 15c. per ton. This represents a very considerable saving of money in a plant smelting 400 or 500 tons of ore per day and producing about 100 tons of matte.

*Mining engineer, Helena, Mont.

THE KILKER MATTE-TAPPING CAR DEVELOPED AT EAST HELENA, MONT.

DUMPING MATTE FROM THE KILKER MATTE-TAPPING CAR TO RAILROAD CARS - HAND SLEDDING ELIMINATED

Practical Test of a Tunnel Boring Machine

The Machine Chips away Entire Face of Tunnel with Chisel Bit Drills;
Advanced 3 1-2 Inches in 10 Minutes During Recent Test

BY JOHN TYSSOWSKI

Many efforts have been made to solve the problem of designing a machine to rapidly cut tunnel headings. Since 1853 over 30 machines have been tried and proved failures, in every case some practical consideration or vital principle in construction having been overlooked. Recently the Karns, Sigafos, Proctor, and Granger designs have attracted attention. The Terry, Tench & Proctor tunneling machine, the joint production of O. S. Proctor, of Denver, and E. F. Terry, of the Terry & Tench Company, contractors, New York, is now receiving a practical test in excavating a drain tunnel for the New York Central excavation

number on the outer circumference of the circle; this will allow the entire face to advance at a more uniform speed.¹

DESCRIPTION OF TUNNELER

Fig. 2 shows the machine in position at the start of the tunnel in the New York Central excavation. Fig. 1, reproduced from *Engineering News*, Nov. 19, 1908, shows diagrammatically the construction of the tunneler. It weighs 15 tons, is about 25 ft. long over all, and cuts a tunnel 8 ft. in diameter. At the rear, the mechanism is carried on a four-wheel truck running on a 22-in. track of light T-rails; the front end is carried on

air engine and worm gearings on the truck, the reduction being 5000 to 1, the length of feed 14 ft., and the maximum speed at which the machine can be moved 8 in. per min. At the rear end of the main hollow shaft are adjusting screws by means of which the yoke bearing the rear end of the frame is moved, thus regulating the horizontal and vertical directions of advance. The head of the machine is rotated by another compressed-air engine and train of gearing. During the trial run, the head made one revolution every 1 3/4 min., the drills traveling at speeds ranging down from a maximum of 0.25 ft. per sec.

FIG. 1. DIAGRAMMATIC REPRESENTATION OF MACHINE

near Forty sixth street, New York. At a trial run made June 3, 1909, this machine succeeded in advancing an 8-ft. heading 3 1/2 in. in 10 min., chipping away the entire face of the rock, a fairly tough and compact mica schist. The machine was operated under 80 lb. air pressure, whereas the designers claim it should have 100 lb. of air. The tunneler ran without any hitch, and was stopped only when a stringer of quartz was encountered on the outer rim of the heading and was found to hold the machine back. Two more drills or groups of hammers will be added to cover the outer portion of the circle excavated, thus doubling the

two conical wheels that fit the surface of the excavation. A 20-in. I-beam laid flatwise forms the frame of the machine. The forward end of the beam rests on the front truck while the rear end bears a yoke casting carried adjustably on the rear truck. The tunneler is fed forward and kept up to its work by a double (staggered) spur gear, journaled on the truck, which engages a line of duplex rack rails laid midway between the rails upon which the machine is carried. The feed is operated by means of a compressed-

From the hub of the main head radiate four arms which connect to the outer casings of the head and four bars that carry the pneumatic drills. Air is conveyed to the drills from the central bore of the main hollow shaft, by air-hoses connected to valved branches on the forward end of the shaft.

The hammers are arranged so as to chip away the entire face of the entry. At present there are 25 of these drills each carrying four chisel bits on the machine, but as stated above, two more will be added in order to insure the outer periphery of the circular heading being cut as rapidly as other portions. The drills

¹Since this article was written it has been found necessary to remove the machine in order to make the necessary changes.

FIG. 2. THE TUNNELER IN POSITION FOR TRIAL IN NEW YORK CENTRAL EXCAVATION

have spool valves, and are air cushioned at either end of the cylinder, a very important consideration in work of this class where portions of the headings may be of soft material while others are hard rock. Fig. 3 shows in a general way the form of air tool used on the tunneler. The chuck has been slightly modified, however, and the air cushions are merely indicated as occupying the spaces formerly used for springs.

HANDLING THE DEBRIS

Steel plates placed between the hammers form pockets into which the chipings are caught; these pockets discharge into a hopper at the rear of the rotating head. The debris is carried to the rear of the machine by a conveyer belt driven by the forward air-engine. Four rails will be laid behind the machine, the central two being spaced 22 in. so as to carry the rear truck of the machine while the outer two, spaced at 18 in. gage, form tracks for muck cars. Switching facilities will have to be provided. A waterspray

little timbering would be required in good ground.

The designers claim an air consumption of 3000 cu.ft. per min., and estimate that the machine can be operated at a cost of \$300 per day. They also hope to excavate from 1256 to 3768 cu.ft. of rock per day, which means an advance of from 25 to 75 feet.

Power Development in Colorado

A great work, and a still greater boon to the miners of the State, is that of the Central Colorado Power Company, which has been quietly spending millions in controlling and developing the power contained in the streams of the State and delivering it to the mines, thus lowering the costs of mining and milling, and increasing the production by enabling an immense tonnage of low-grade ores to be marketed at a profit, which otherwise would not pay to extract or treat. This will be more readily realized when it is stated that the above company is supply-

that 4000 h.p. are being transmitted to Leadville and Summit county mines, mills and dredges, and several thousand horsepower are also sent to the Boulder county mines. At this plant, the water is conveyed from the intake at the diverting dam through a tunnel 11x16 ft. in the clear, and 12,700 ft. in length, the bottom and sides being lined with concrete. It has a capacity of 1250 cu.ft. per sec. and gives a head of 105 ft. The power house is equipped with two 9000-h.p. turbines, each direct connected to a 5000-k.w., three-phase, 60-cycle, alternating current generator, giving a total of 18,000 h.p. It is the purpose of the company to extend the tunnel later on, and the ultimate resulting capacity will be from 30,000 to 40,000 horsepower.

On Middle Boulder creek, about thirty miles northwest of Denver, another plant is under construction. This consists of a reservoir with a capacity of 500,000,000 cu.ft., the water to be conducted 12 miles through a concrete pipe 36 in. in diameter, to a terminal reservoir, from

FIG. 3. GENERAL FORM OF THE AIR DRILLS

plays on the face of the heading, thus keeping down the dust.

In the test one engineer and three helpers were employed but when the device for handling the chipings is perfected the designers claim that only one helper will be required. Providing that the machine operates 20 hours out of the 24 and maintains the speed attained in the recent test, it would make an advance of 35 ft. per day. However, it must be borne in mind that this machine must cut away over 100 times as much as is ordinarily cut by drills in driving a tunnel, and that the opportunities for breakage and disablenents of the machine are multiplied many times. Only a practical working test covering a long period of time (such as is now being started) will serve to demonstrate the future usefulness of this machine. The great advantages to be derived from the successful operation of such a tunneler would be in the rapid rate of advance attained, at a probable lower cost than is now possible, and the desirable form of tunnel cut. With the circular cut, in a natural arch, comparatively

ing power at \$75 per h.p. per annum which would cost the mines from \$100 to \$150 to make by steam. An additional advantage, as proved by the past severe winter, lies in the fact that a great many of the mines were idle through inability to get their supplies of coal to the mines, whereas those which obtained their power from the electric power company worked along steadily.

The benefits which will accrue to other industries are enormous, but these being outside the province of the JOURNAL, need not be here enumerated. In the category of benefits conferred on the mining industry, however, must be included the supplying to Denver the great mart of supplies and machinery of part of the power for the Denver Gas and Electric Company, a contract for which was signed last December involving a sum of \$200,000 yearly. It is expected that the Central Colorado Power Company will begin supplying this power in a few days.

The hydroelectric generating plant at Shoshone, near Glenwood Springs, on the Grand river, has been so far completed

which the water will be sent to the power plant through a steel pressure pipe 9500 ft. long, the resulting head being about 1850 ft. The power house will contain two impulse waterwheels, with a total capacity of 21,000 h.p., each of which wheels will be connected to a generator of about 10,000 h.p. This plant is expected to be completed this year.

Still another development is at Gore cañon, on the Moffat road, about 120 miles west of Denver. This will have a diverting dam on Grand river, a tunnel 5 miles in length, giving a head of 350 ft., and a capacity of from 20,000 to 30,000 h.p. The Leadville, Boulder, Breckenridge, Georgetown, Idaho Springs, Dillon and other mining camps in the northwestern portion of the State will be supplied from the above plants. At the beginning, the management of this great enterprise left much to be desired, but its ultimate successful construction is due to the skill and efforts of Frederick A. Abbott, chief engineer, and G. H. Walridge, general manager, both of New York.

Patents Relating To Mining and Metallurgy

A Selected and Classified List of New Inventions Described during the Past Month in the Publications of the Patent Offices

UNITED STATES AND BRITISH PATENTS

A copy of the specifications of any of these patents issued by the United States Patent Office will be mailed by The Engineering and Mining Journal upon the receipt of 25 cents. British patents are supplied at 40 cents. In ordering specifications, correspondents are requested to give the number, name of inventor and date of issue.

COAL AND COKE

COKE—Means for Supplying Air to Coke-Ovens. John H. Hillman, Pittsburg, Penn. (U. S. No. 924,462; June 8, 1909.)

COKE-DRAWER. Harvey Cory, Pittsburg, Penn. (U. S. No. 923,410; June 1, 1909.)

COKE—Process of Obtaining Ammonia and Tar. Heinrich Koppers, Essen-on-the-Ruhr, Germany. (U. S. No. 12,071; June 8, 1909.)

COKE-DRAWING APPARATUS. Charles M. Clarke, Pittsburg, Penn., assignor to Hebb Coke Drawer Company, Uniontown, Penn., a Corporation of Pennsylvania. (U. S. Nos. 923,133 and 923,140; June 1, 1909.)

COKE-OVEN. George W. Thompson, Collinsville, Ill. (U. S. No. 924,293; June 8, 1909.)

MINING-MACHINE—Electric Coal-Puncher or Mining-Machine. John H. Thompson, Charleston, W. Va., assignor to Johnson Electric Machine Company, Charleston, W. Va., a Corporation of West Virginia. (U. S. No. 922,736; May 25, 1909.)

PEAT—Improvements in Elevators Applicable to Apparatus for the Production of Peat Fuel. Andrew Kesson, Lynedock, Scotland. (Brit. No. 23,392 of 1907.)

COPPER

PURE COPPER—Process for Obtaining Pure Metallic Copper from a Solution of a Salt of Copper. Lucien Juman, Paris, France. (U. S. No. 924,077; June 8, 1909.)

PURE COPPER—Process for Obtaining Pure Copper. Lucien Juman, Paris, France. (U. S. No. 924,076; June 8, 1909.)

GOLD AND SILVER

ALLUVIAL MINING—Method of Recovering Values from Alluvial Deposits. Ole T. Crosby, Nome, Alaska. (U. S. No. 923,116; May 25, 1909.)

FILTER PRESS. Samuel K. Behrend, Denver, Colo. (U. S. No. 924,131; June 8, 1909.)

PAN-RIFFLER. John M. White, Selma, Ore. (U. S. No. 923,932; June 1, 1909.)

PULP-AGITATOR. William C. Paterson, Denver, Colo., assignor, by direct and mesne assignments, to the Rapid Cyanide Extraction Company, a Corporation of Colorado. (U. S. No. 923,571; June 1, 1909.)

IRON AND STEEL

ELECTRIC FURNACES—Improvements in or Relating to Electric Furnaces for the Manufacture of Steel. Adolphe Hugo, Pirminy, France. (Brit. No. 12,258 of 1908.)

ELECTRIC TEMPERING-FURNACE. Vernon Royle, Paterson, N. J. (U. S. No. 924,109; June 8, 1909.)

MANUFACTURE—Method of Consolidating Fine Dust for Use in the Manufacture of Steel. William Thomlinson, Seaton Carew, West Hartlepool, England. (U. S. No. 923,605; June 1, 1909.)

SLAG—Machinery for Conveying Blast-Furnace Slag. Edward A. Debag, Passaic, N. J. (U. S. No. 923,218; June 1, 1909.)

TREATMENT OF STEEL—Process for the Treatment of Steel for Industrial Purposes. La Société Schneider & Cie, La Creusot, France. (Brit. No. 24,244 of 1908.)

NICKEL

ORE TREATMENT—Process of Treating Nickel Ores. Anson G. Betts, Troy, N. Y. (U. S. No. 923,003; May 25, 1909.)

MINING—GENERAL

BORE HOLES—Improvements in or Relating to Waterproof Lining for Bore Holes. Maurice Bodart and the Deutsche Solvay-Werke Aktiengesellschaft, Prussia, Germany. (Brit. No. 21,197 of 1908.)

FIRE EXTINGUISHING—Method of Extinguishing Fires in Mines. Frank T. Byers, Mount Pleasant, Penn. (U. S. No. 924,589; June 8, 1909.)

SHAFT SINKING—Sinking Shafts and the Like. Daniel E. Moran, Mendham, N. J. (U. S. No. 923,984; June 8, 1909.)

VENTILATION—Gas-Extractor and Mine-Ventilator. George Laws, Phillipsburg, Penn. (U. S. No. 922,603; May 25, 1909.)

ORE DRESSING—GENERAL

CLASSIFIERS—Improvements in or Relating to Classifiers or Separators for Minerals of Different Specific Gravities. Creighton Churchill, Brookline, Mass. (Brit. No. 7841 of 1908.)

CONCENTRATION—Method for Concentrating Ores. Albert H. Stebbins, Little Rock, Ark. (U. S. No. 923,455; June 1, 1909.)

CONCENTRATORS—Improvements in Ore Concentrators. Communicated from Charles W. Eccleston, Los Angeles, Cal. (Brit. No. 19,163 of 1908.)

CRUSHING-ROLLS. Arthur E. Hogue, Toronto, Ontario, Canada. (U. S. No. 924,352; June 8, 1909.)

ELECTROSTATIC SEPARATING PROCESS. Lucien I. Blake, Lawrence, and Lawrence N. Moscher, Needlesha, Kan., assignors to the Mining and Milling Company, Denver, Colo., a Corporation of Maine. (U. S. No. 924,032; June 8, 1909.)

ORE-PULVERIZER. George P. Good, Detroit, and William L. McCullough, Ypsilanti, Mich., assignors to the W. L. McCullough Company, Ypsilanti, Mich., a Corporation of Michigan. (U. S. No. 922,577; May 25, 1909.)

ORE-JIGGER. William M. Williams, Gridley, Cal., assignor of one-half to J. L. Miola, Gridley, Cal. (U. S. No. 923,917; June 8, 1909.)

ORE-SEPARATOR. Charles M. Mullen, Baker City, Ore. (U. S. No. 923,988; June 8, 1909.)

ORE-SEPARATOR. Elmer A. Ross, Ticonderoga, N. Y., assignor of one-fourth to Decus C. Bascune, Ticonderoga, N. Y. (U. S. No. 919,246; April 20, 1909.)

WATER-JIG. Gelasio Cactani, Kellogg, Idaho. (U. S. No. 923,328; June 1, 1909.)

METALLURGY—GENERAL

BRIQUETTING—Improvements in the Process of Briquetting Ore with Blast-Furnace Slag. Wilhelm Lessing, Trolsdorf, Germany. (Brit. No. 18,680 of 1908.)

PHYSICAL PROPERTIES—Improvements in and Relating to Processes for Improving the Physical Properties of Metals and Their Alloys. David Lamson and Theodore H. Thomas, Denver, Colo. (Brit. No. 12,452 of 1908.)

PRECIPITATION—Method of Thionous Precipitation of Copper and Silver from the Solutions. (U. S. No. 923,516; June 8, 1909.)

REFRACTORY ORE TREATMENT—Method of Reducing Ores. Frederick M. Beckett, Niagara Falls, N. Y., assignor to Electro Metallurgical Company, New York, N. Y., a Corporation of West Virginia. (U. S. No. 924,130; June 8, 1909.)

MINING MACHINERY AND APPARATUS

AIR-COMPRESSOR. Electric Air-Compressor. Augustus J. Pocco and Richard E. Algire, Dayton, Ohio, assignors to the Platt Iron Works Company, Dayton, Ohio, a Corporation of Ohio. (U. S. No. 918,149; April 13, 1909.)

CONVEYING MACHINERY—Improvements Relating to Conveyer Apparatus, More Particularly for Conveying Ore and Stuff from Shallow Lodes. Paul Töniges, Berlin. (Brit. No. 610 of 1908.)

DRILL. Martin Hardsocg, Ottumwa, Iowa. (U. S. No. 922,513 and 923,514; June 1, 1909.)

HEAVING APPARATUS for Open-Air Mining. Emil Wichow, Lubbeck, Germany. (U. S. No. 919,105; April 20, 1909.)

MINE CAGES—An Improvement Applicable to Pit Cages and Hoists. James Harrison,

Clayton; Richard Oliver, Bewick, and Edward Peters, Manchester, Eng. (Brit. No. 13,95 of 1909.)

MINE-CAR BRAKE. Isaac Glen, Trafford City, Penn. (U. S. No. 923,260; June 1, 1909.)

MINER'S CANDLESTICK. Charles J. Ramstead and Peter J. Johnson, Ourgy, Colo. (U. S. No. 922,950; May 25, 1909.)

MINERS' LAMPS—Reflector for Miners' Lamps. Zachariah Bough and Leslie F. Weaver, Hanning, Penn. (U. S. No. 923,655; June 1, 1909.)

MINERS' LAMPS—A Stand for Miners' Lamps. John Hardy, West Hartlepool, Eng. (Brit. No. 17,700 of 1908.)

MINING TOOL—Combined Mining and Track Tool. William L. Groom, Coal Valley, Ala. (Brit. No. 23,391 of 1908.)

ROCK DRILLS—Improvements Relating to Rock Drills. George H. Rayner, Nether Edge, Eng. (Brit. No. 25,926 of 1908.)

TIMBERING—Reinforced Concrete Mining-Timbers. John A. Elliott, Butte, Mont. (U. S. No. 924,153; June 8, 1909.)

METALLURGICAL MACHINERY AND APPARATUS

ELECTRIC FURNACE. Frédéric M. Chaplet, Laval, and Alexandre Rémond, Paris, France. (U. S. No. 923,918; May 25, 1909.)

ELECTRIC FURNACES—Improvements in Electric Furnaces. Charles E. Knowles, Holmdale, Eng. (Brit. No. 13,502 of 1908.)

ELECTRIC FURNACES—Improvements in Electric Furnaces. Erik Cornelius, Trollhättan, Sweden. (Brit. No. 10,378 of 1908.)

FURNACE for Gasifying Coal, Roasting Ores and the Like. Hanns Kies, Munich, Germany. (U. S. No. 922,942; May 18, 1909.)

FURNACE—Revolving Furnace for Volatilizing Ores. Harry H. Hughes, Springfield, Mo. (U. S. No. 922,906; May 25, 1909.)

ORE-TREATING FURNACE. Chauncey C. Medbery, New York, N. Y. (U. S. No. 922,609; May 25, 1909.)

POWDERED FUEL—Improvements in or Relating to Apparatus for Supplying Fuel in Powdered or Similar Form in Furnaces. Otto Trotsch and Mrs. E. Robinson, London. (Brit. No. 4255 of 1908.)

PRECIPITATION—Apparatus for Use in Solution and Precipitation Processes. Woldemar Hommel, London, England, assignor to Metals Extraction Corporation, Limited, London, England. (U. S. No. 918,749; April 20, 1909.)

PRECIPITATION—Improvements in, or Relating to Apparatus for Use in Solution and Precipitation Processes. Woldemar Hommel and the Metals Extraction Corporation, Ltd., London. (Brit. No. 24,017 of 1907.)

REVERBERATORY REGENERATIVE FURNACE. Thomas S. Blair, Jr., Elmhurst, Ill., assignor to the Blair Port Company, New York, N. Y., a Corporation of New York. (U. S. No. 922,939; reissue; April 13, 1909.)

ROASTING FURNACES—Improvements in, or Relating to Mechanical Roasting Furnaces. Roman von Zelowski, Engla, Belgium. (Brit. No. 15,192 of 1908.)

ROASTING FURNACE—An Improved Rotary Roasting Furnace. John R. Swensen and Frederick J. Morgan, Swansea, Wales. (Brit. No. 12,825 of 1908.)

ROASTING-FURNACE. John E. Greenawalt, Denver, Colo. (U. S. No. 919,090; April 20, 1909.)

ROASTING-FURNACE. Frank E. Marcy, Salt Lake City, Utah, assignor to Frank Klepetko, New York, N. Y. (U. S. No. 920,971; May 11, 1909.)

ROTARY ORE-EXTRACTOR. Jesse O. Blackburn, Chula, Ariz. (U. S. No. 923,319; June 1, 1909.)

SNIFFLER SMOKE—Apparatus for Condensing and Purifying Smoke, etc. Selden I. Clawson, Salt Lake City, Utah. (U. S. No. 922,260; May 18, 1909.)

SMOKE PREVENTION—Improvements in Smoke Consuming Devices for Furnaces. Immanuel Bausch, Karlsruhe, Germany. (Brit. No. 18,859 of 1908.)

Personal

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

A. F. Kuehne is in New Mexico on professional business.

Frederick H. Morley, of Denver, Colo., is visiting New York.

Charles G. Yale, of San Francisco, is in New York on a visit.

Arthur James, of New York, has been visiting Morenci, Arizona.

W. G. Trethewey, of Toronto, is inspecting mining properties in the Sturgeon lake area.

Prof. William P. Blake has been reappointed territorial geologist of Arizona for another term.

President J. H. Plummer, of the Dominion Iron and Steel Company, has sailed for England.

F. F. Sharpless is at Placerville, Cal. He will go thence to Nevada before returning to the East.

Pope Yeatman has gone to Alaska and will not return to New York until the middle of September.

O. H. Fairchild, of Denver, has gone to Arizona to examine mining claims near Hot Springs Junction.

Kirby Thomas, of Mexico City, is examining a quicksilver property in the southern part of Mexico.

Robert Schorr has removed his office to the Postal Telegraph building, Market and Battery streets, San Francisco.

H. F. Fay, president of the Allouez and the Centennial copper companies of Michigan, is a visitor at these properties.

Robert H. Richards, of Boston, is devoting two or three weeks to professional work in and about Denver, Colorado.

J. A. Skeene has been appointed superintendent of the Pan Silver mine at Cobalt, Ont., in place of M. McCallum, resigned.

J. Morgan Clements, of New York, has gone to New Mexico on professional business. He expects to be absent about three weeks.

James W. Myers has returned to Golden, Colo., after a year and half visit to New Zealand, in the interests of a large mining company.

B. Leyson has resigned as manager of the City of Cobalt Mining Company at Cobalt, Ont., and will develop some claims in the Montreal river country.

Dr. Henry M. Ami retires at the end of June from the Geological Survey of Canada after a continuous service of 28 years, on account of failing health.

Herbert S. Crocker and Milo S. Ketchum have formed a partnership under the title of Crocker & Ketchum, as consulting engineers, with offices at 811 Seventeenth street, Denver, Colorado.

C. B. Ireland, of Georgetown, Colo., has been appointed general manager and superintendent of the Atlantic Mining and Milling Company, operating in the Atlantic district in Clear Creek county, Colorado.

Morton Welber has been engaged as consulting engineer for the firm of Weir Brothers & Co., New York, for a period of two years. He has had experience in several countries in the examination of mines.

Arthur K. Adams, for the past two years professor of geology at the New Mexico School of Mines, Socorro, N. M., is now a mineral inspector for the General Land Office, with headquarters at Huron, South Dakota.

Hon. William Templeman, head of the Mines Department of Canada, has gone to the Pacific coast, and during the summer will visit the Yukon, accompanied by R. W. Brock, director of the Canadian Geological Survey.

Selwyn Goldstein, formerly manager and engineer of the Great Boulder Proprietary mine in Western Australia, is in Mexico representing British interests. His address is care Banco de Londres y Mexico, Mexico City.

S. E. Bretherton has returned to his office in San Francisco from a trip of several weeks on business in connection with the Friday-Lowdon Copper Company and the Afterthought Copper Company, of Shasta county, California.

Alfred Campion has been appointed lecturer on iron and steel metallurgy at the Technical College of Glasgow, Scotland, and John S. G. Primrose lecturer on assaying and treatment of the precious metals. They succeed Professor Sexton, who has resigned.

Charles H. Clapp, who during the season of 1908, commenced a geological and topographical survey of the southern portion of Vancouver island, has returned to the island to continue this work, which is under the auspices of the Geological Survey of Canada.

W. J. Sutton, of Victoria, has been authorized by the Geological Survey to report on the rocks of the east coast of Vancouver island. As geologist for the Dunsmuirs, chief owners of large coal mines, Mr. Sutton has already done much geological work on the island.

Guy C. Barton, at one time president of the Omaha & Grant Smelting Company, died at Omaha, Neb., June 15. He was prominent in the organization of the American Smelting and Refining Company, but held no office in that company.

Captain Johnson Vivian, one of the pioneers of the Lake Superior copper district, died at his home at Houghton, Mich., June 17, at the age of 80 years. Captain Vivian was born in Cornwall, England, in 1829, and spent his early life in the mines in that county. In 1853 he came to the United States and located in Keweenaw county, Mich., where he worked as a miner. His rise was rapid; he had been chief mining captain and agent for several of the mines in the Lake Superior district, among which were the Copper Falls, the Hancock, the Franklin and the Huron.

D. V. A. Williams died in Los Angeles, Cal., May 16, as the result of hardships incurred while lost on the California desert some months ago. He was 56 years old. He was born in New York, but removed to Joliet, Ill., when a young man. In 1879 he went to Leadville, Colo., and engaged in mining. Later he was 16 years in Mexico, where he had charge of the development of several mining claims. After leaving Mexico he went to southern California, making his headquarters at Johannesburg. For some time he had been president and general manager of the Sydney Group Mining Company.

Societies and Technical Schools

Western Association of Technical Chemists and Metallurgists—A dinner will be given July 2 at the Brown Palace hotel, Denver, in honor of Professor and Mrs. Robert H. Richards, of Boston, who will both speak on subjects relating to their work in chemistry and metallurgy.

Engineers' Society of Pennsylvania—At the meeting held in Harrisburg, June 12, it was decided to form a general State society of engineers, to be recognized by the legislature of Pennsylvania with authority to restrict practice to men of competence in their lines. The convention was held under the auspices of the Engineers' Society of Pennsylvania, having headquarters in Harrisburg, and was attended by delegates from the Engineers' Club of Philadelphia, the Engineers' Society of Western Pennsylvania, and the Engineering Society of Northwestern Pennsylvania. Resolutions were adopted providing that each of the societies participating should name a committee of three to form a general committee to meet in Harrisburg prior to October next and organize for the purpose of framing a code to be submitted at a convention to be held in the summer of 1910. Engineers of all branches in the State will be invited to become members.

Obituary

Colonel Charles C. Mattes died at Scranton, Penn., June 8, aged 51 years. He was for a number of years connected with coal interests in the Wyoming valley, and was general manager of the Lackawanna Coal and Iron Company.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Denver, Salt Lake City, Goldfield, Colbalt, Mexico

REVIEWS OF IMPORTANT EVENTS

San Francisco

June 18—A company has been formed in San Francisco to furnish electric power for mining districts in Sierra county. A dam has been built two miles above Downieville, which is 21 ft. high and stood the flood waters of last winter. The water rights are mainly on the south fork of the North Yuba river between Downieville and Sierra City these having been taken up by W. A. Lotspeich and Con. York, of Downieville. The site for a power-house on Durgan Flat has been selected. Foreign capital has agreed to take the bonds. A power line from this plant will soon be built to Forest and Alleghany, where such rich development among the mines has lately taken place.

Interest in the gold discoveries in reopened old mines at Alleghany and Forest, Sierra county, still continues. L. P. Woodbury, of the Rainbow has financed his mine in Colorado and is now starting in on a large scale. More rich ore is being taken out than at first. The Red Star ledge, also handled by Mr. Woodbury, will be actively developed. A tunnel is being driven ahead to intersect the Tightner vein. The El Dorado is still turning out jewelry ore, as is the now famous Sixteen-to-One. The old Wm. Irelan claims have been bonded to C. C. Ward and will now be worked after over a quarter of century of idleness. They paid well as far back as 1853 when they were located. At Forest, in the same county, many claims have lately been placed under bond to different parties. Good ore has been found in the Lucky Point and in the Davis & Phippen claim. The Hunch vein, paralleling the Plumbago and Rainbow mines, is to have a tunnel started for the vein. At Perry Bixby's mine below Forest, a 2-ft. vein carrying ore running up into the hundreds per ton has been found.

In Yuba county also there is quite a mining revival. For a long time this county produced millions from its hydraulic mines, but when they were closed down mining languished for years. Then came the dredge men who have developed an extensive industry along the river and one which is increasing in importance yearly. At Brownsville and Browns Valley several promising quartz mines are being operated and some others of the old mines are being reopened. In these places, as well as at Smartsville, Indiana ranch and Camptonville, scores of prospectors have gone to work this summer.

Butte

June 17—The report of the Amalgamated Copper Company for the fiscal year ending April 30, 1909, has recently been published. The report states that electrical power is being used for operating the mine pumps and that experiments are now being made to ascertain the feasibility of operating the hoisting engines by compressed air generated by electricity. The net income is stated to have been \$3,633,980, as compared with \$6,670,557 for 1908, and \$14,154,400 for 1907. The dividends were \$3,077,758 as compared with \$6,155,516 in 1908, and \$11,926,312 in 1907. The surplus was \$586,222, as against \$525,041 in 1908 and \$2,228,088 in 1907. The liabilities are as follows: Capital stock, \$153,887,900; accounts payable, \$22,565; dividends payable in May, \$769,439; surplus and reserve, \$12,595,045.

In the suit of the Butte Water Company against the Reins Copper Company, a default judgment against the mining company was recently entered for the sum of \$598. The Columbia-Butte Mining Company has begun action against Henry T. Heyder to recover \$60,000 damages. In its complaint the company states that in 1908 it paid to defendant \$50,000 for the Morning Star, Evening Star, Columbia, Germania and Washington lode claims, which were deeded to it by defendant, but that the defendant never in fact was the owner of the Evening Star and Washington claims and owned only one-fourth of the Columbia. The complaint states that the value of the property for which the defendant was unable to give a title was \$30,000 and that, owing to its inability to put through a deal with all of the property it was damaged to a further sum of \$30,000.

In the adverse suit of Allen Giberson against the Tuolumne Copper Mining Company, the local district court has decided that the plaintiffs own the quartz claim in dispute. The plaintiff claimed the ground under the Merrimac location and the defendant under the Smoky Moke location. In the case of the Milwaukee Gold Extraction Company against George W. Gordon and C. A. Brooks for the possession of the Big Bill quartz claim located in Granite county, Judge H. L. Meyers, of the local district court, has decided that the claim belongs to the defendants. The latter part of last week the new stack at the Boston & Montana smelter, at Great Falls, was put in use. The stack is 506 ft. in height and is the

largest in operation in the world. It has been in course of construction since the fall of 1907.

Denver

June 19—The Golden Cycle company operating the mine of the same name in the Cripple Creek district and the mill at Colorado City has paid the final instalment for assuming control of the Pike's Peak Fuel and the Central Fuel companies. The former corporation owned the Pike View, Danville and Williamson coal mines, north of Colorado City, comprising 2500 acres and furnishing most of the coal output for the immediate vicinity. The Golden Cycle company also controls about 11,000 acres farther east held in the name of the East Colorado Coal and the East Colorado Springs Land companies and it will now be in a position to proceed with the construction of the projected electric power plant near the Pike View mine. It is stated that \$200,000 will be spent in the initial unit and that power will not only be furnished for the Golden Cycle mill but that a franchise will be asked from the city with the purpose of entering the local public lighting and power field. Through its coal companies, the Golden Cycle company will sell coal to the mines in the Cripple Creek district.

The Modern Smelting and Refining Company, which is constructing a copper-smelting plant, two miles beyond Argo, at Utah Junction, will double the capacity of the plant as soon as the first unit is put in operation. The identity of the interests behind this plant has been a matter of some speculation in this vicinity. The plant is being constructed under the direction of Henry C. Reno and the company is incorporated for \$2,500,000. The plant will have railroad connections with the Moffatt road, the Colorado & Southern and the Burlington.

Last Spring the Cleveland shaft at Leadville was sunk to a depth of 825 ft and drifts started north and south from the shaft to cut the vein. The flow of water was so heavy that work was temporarily abandoned and drifts started at the 690-ft. level. After driving about 125 ft., in the Cambrian quartzite, the vein has been opened, showing 4 ft. of mineral, with the hanging-wall not yet exposed. Since the opening of the vein the work of timbering to secure the ground has been in progress; when this is completed the vein will be thoroughly explored. The character of the ore is similar to that found above in

the porphyry, and is of smelting grade. The opening of this fissure in the Cambrian quartzite is the most important event of the season in this camp.

Salt Lake City

June 18—The Daly-West company has posted the second quarterly dividend of 30c. per share and amounting to \$54,000. The reports show a surplus of \$391,283 at the end of the first quarter. A station is now being cut on the 1700-ft. level, and a crosscut to the vein will soon be under way at that point. It will require about 900 ft. of work to reach the ore. The drift to the drain tunnel should reach the ledge within the next 400 ft., while about 200 ft. will make connections in the shaft. It is expected that this work will be finished in about 90 days.

The litigation in connection with the Daly-West company is creating much interest. The Otto Hanke, John J. Daly, and H. R. McMillan interests have applied to the District Court for an alternative writ of mandate to examine the Daly-West books and the management now charges that this faction is not acting in good faith but for the interests of the Daly-Judge, a rival company, which owns adjoining ground in Park City. The charge is made that Hanke, Daly and McMillan are stockholders in the Daly-Judge, and it is alleged that they are planning to get this information for the purpose of seeking to control the company for the interests of the Daly-Judge company.

The Colorado, Sioux Consolidated and Iron Blossom companies, owning properties in the Tintic district, posted dividends on June 10 aggregating \$210,000. The Sioux Consolidated announced a dividend of 7c. per share, and the Colorado and Iron Blossom will pay 8c. each on the shares issued. The latter company passed its dividend in May and the present dividend of 8c. amounting to \$80,000 was something of a surprise. It is understood, however, that the company is now producing a good tonnage of high-grade ore, some of which is of better grade than the mine previously produced.

The shares of the Tintic Humboldt Mining Company were recently listed on the exchange. The company is capitalized for \$100,000 and owns 10 unpatented claims in the North Tintic mining district three miles from the railroad. Thomas J. Pierpont is president of the company, and the development on the property consists of 80 ft. of shaft and 75 ft. of tunnel work, together with surface improvements. The stock of two other Tintic companies, the McKinley Mining Company and the Eureka Mining Company, was listed on the Exchange last week. The latter company has eight claims in the East Tintic district and is headed by Robert A. Brown, superintendent of the Centennial Eureka mine.

Goldfield, Nevada

June 16—The authorities of Esmeralda county are making a strong effort to rid the county of "wildcat" miners and grafters. The district attorney, August Tilden, formerly of San Francisco, is looking into everything and seeing that all business for the county is conducted on a fair and square basis. Many of the county officials have been indicted and are out on bonds. The county commissioner from Rawhide, as well as the officials of the defunct bank are implicated.

It is rumored that the district attorney's office has evidence which will amply support the alleged indictments against the officials and directors of certain mining companies, and that this evidence shows a criminal conspiracy on the part of the company to defraud the county and State of their bullion tax.

Cobalt

June 19—The Nipissing Central Railroad Company, which has the franchise for building an electric line between the towns of Cobalt and New Liskeard, has started work on construction. The contract has been let to the Nova Scotia Construction Company, of Sydney, C. B., and it is estimated that the cost will be \$125,000. Power will probably be obtained from one of the companies bringing it into the camp. This road will be a great boon to the towns of Haileybury and New Liskeard, as numbers of people now living in Cobalt, will move to the former places, where the natural advantages are much greater. The construction of the line was strongly opposed by Cobalt.

Considerable uneasiness was caused in the early part of the week by bush fires which were burning near the town. At one time the magazines of the Hamilton Powder Company and the Buffalo mine were in danger and also the buildings of the Temiskaming & Hudson bay. A change of wind, however, averted the danger.

Charles Clinton, of New York, has disposed of his interest in the Clinton property, west of the Cobalt Gem, to New York parties.

The Station Grounds Mining Company, owning a narrow strip of land along the right of way of the Temiskaming & Northern Ontario railroad has, up to date, located 18 surface veins, in some of which a little native silver can be seen. The property is seven-eighths of a mile long and varies in width from 90 to 256 ft. As soon as the hydraulic air is in camp two shafts will be started. It will be necessary to purchase the land on which the shafts are to be sunk, as the Railway Commission will not allow them to be sunk on the right of way. The company was purchasing power from the Cobalt Lake and operating one of the shafts, but owing to the expense, these operations have been suspended.

The Monarch claim, west of Sasaginaga lake, has been taken over by New York parties and a force of men will start work on development in a few days' time.

The Temiskaming & Hudson Bay directors have definitely decided to increase the capitalization to \$3,500,000, although the final details have not yet been arranged. During the summer a concentrator of about 30 tons capacity will probably be erected.

The Davis Mines, Ltd., owning 170 acres in South Coleman, is following the lead of the Peterson Lake Company and leasing the property in small lots. Three leases have already been executed to the Shamrock, Armstrong and Jacobs parties, while negotiations are under way for others.

Gowganda, Ontario

June 18—There has been a good deal of disappointment in the Gowganda district this spring, as the number of people going into the country was not so great as anticipated. More attention is being paid to the Miller, Everett and Shanty Lake sections, and so far they appear to be the most promising of the new districts. The Everett Silver Cobalt Syndicate, has erected two permanent camps at Everett Lake and is employing 100 men. This company owns 21 claims. A find of silver was made on the Cartwright claim, adjoining the Blackburn, at Everett Lake and the vein was traced from the latter property. The Blackburn is one of the best mines in the district and now has a complete plant running. On McRae's property at Shanty Lake, there is silver showing in 11 veins and considerable development has been accomplished. The German Development Company, has a force of men engaged on its claims. On the Burns claim in the same section, a new 2-in. vein of high-grade silver has been encountered.

Toronto

June 19—The Ontario government has disposed of 15 parcels of land, aggregating 283 acres, out of 870 acres of the Gillies Limit adjoining the Cobalt district, recently offered for sale. In all 116 tenders were received, but 100 were rejected as being too small. The total sum received is \$74,643. There was no information given as to the value of the land or as to present condition and prospects of the Provincial mine on the limit, so that the sale excited but little interest among mining men. The land is sold subject to a royalty of 10 per cent. on the output and under working conditions.

The Temiskaming & Northern Ontario Railway Commission proposes to make several extensions of the line, including industrial spurs at New Liskeard and Haileybury and has ordered plans and estimates to be prepared for an extension to Elk Lake and Gowganda.

Mexico

June 19—The Mexican Institute of Mining and Metallurgy will hold its first meeting July 12, at Mexico. A charter membership of 100 has been accepted by the provisional council for full membership. A program of technical papers will be submitted at the first meeting and permanent officers chosen by the charter members.

There is revival of talk of zinc smelting in Mexico since the prospect of the loss of the United States market through the pending tariff on zinc ores has arisen. Several concessions have been granted, and the subject is being investigated in the interests of the zinc producers and from an industrial standpoint. Some of the concessions granted contemplate the use of the new electrical processes. It is likely that the zinc smelter, if situated in Mexico, will be in the northern part where there is an abundance of ore and coal. Mexico imported in 1906, which may be taken as a normal year, zinc in the form of ingots, dust and shavings, 293,280 kg.; in the form of perforated sheets for use in cyanidation, 718,376 kg.; and sheets, 701,071 kg. The zinc for cyanidation is admitted free. This importation summary does not take into consideration the amount of zinc coming into the country in the form of galvanized products. The largest importation of zinc is from the United States. If the zinc-ore tariff results in establishing zinc smelters in Mexico, the United States will lose not only the admitted advantage of the docile Mexican zinc ores but also a good market for the zinc products.

The Magistral smelter at Zacatecas has closed after one month's fitful trial. It is alleged that it was defective in construction and costly in operation. The future plans as to the smelter are not yet made known. The independent operators had looked to this smelter as a buffer for better terms than those now offered by the Aguascalientes and San Luis Potosi smelters.

That the Mexican people intend to do everything in their power to control the oil situation in their country is indicated by the formation of a 25,000,000 pesos company, to be known as the *Compania Mexicana de Petroleo El Aguila, S. A.* (The Mexican Eagle Oil Company, Limited), and of which Guillermo Landa, governor of the Federal district, is president. The company has acquired all the concessions for the development, exploitation and marketing of native crude and refined oils, as well as other kinds of products held by the firm of S. Pearsons & Sons, Limited.

London

June 14—The 50th general meeting of the Institution of Mining Engineers was held in London recently. The president, Dr. B. T. Moore, delivered a presidential

address, selecting the production of coal as his subject. The output in Great Britain in 1907 was 267,000,000 tons and in the United States 428,000,000 tons or 40 per cent. of the total production of the world. The largest exporter of coal was Great Britain, the exports in 1907 being 85,000,000 tons. On the question of the exhaustion of the coal supplies, it was stated that the last Royal Commission assumed a quantity in 1901 of 101,000,000,000 tons in Great Britain, which would be worked out in 300 years. Four new papers were presented at the meeting, namely, (1) on "Electricity in Coal Mines," by Robert Nelson, a paper which drew out a good discussion; (2) "Comparison between the Value of Surplus Gas from Regenerator By-product, Coke Ovens and Steam Produced by the Waste Heat from By-product Coke Ovens; with Special Reference to the Evence-Coppée New By-product Ovens," by Mansfeldt H. Mills; (3) "The use of Concrete for Mine Support," by Prof. W. R. Crane, and (4) "Mining in British Columbia," by Mrs. Rosalind Young.

Paris

June 15—The Mokta-el-Hadid company has published its report for 1908. The output of the African iron mines was practically the same as in 1907, a reduction at the Tenez mine being counterbalanced by the Djebel-Hadid mine and the newly opened quarries of Beni-Saf. Outside of these properties this important company is interested in many others. At Ain-Allega, which is a lead-zinc mine worked with the Ouasta-Mesloulia company, the new ore-dressing plant was started in the second half of 1908 and milled about 4200 tons. The Djebel-Djerissa company, managed by Mokta-el-Hadid, produced 115,000 tons of iron ore during the first year of exploitation; the *Compagnie de Kroumirie et des Nezas*, also managed by Mokta-el-Hadid, is awaiting the completion of a railway to work its iron deposits. The Mokta-el-Hadid has also large investments in the *Compagnie des Phosphates de Gafsa* (Tunis), in the *Compagnie des Minerais de Fer de Krivoi-Rog* (Russia), and in the *Société de la Mouriére*, an iron mine of the Briey district in France. The profits were close to \$800,000, and the company has declared a dividend of 50 fr. per share.

The *Compagnie Industrielle du Platine* did not declare any dividend for 1908. The capital of this company was increased from \$3,200,000 to \$4,000,000 in order to buy the shares of the Platinum company, and thus assist in securing the control the company hopes to have over all the platinum mines of Russia.

Johannesburg

May 15—A paper was read by Malcolm Fergusson, a government inspector of

mines, at the May meeting of the South African Association of Engineers on the "Relation of Safety to Economy in Mining." Some important points were raised and good service will be rendered to the industry by their open discussion. The aim of Mr. Fergusson's paper was to demonstrate that the supervision exercised over underground work upon the mines is inadequate, and that more officials should be employed below to insure safety. Summarizing his views, the author contended that "mine accidents are due to lack of discipline owing chiefly to the fact that there are insufficient officials to supervise the men properly and that the obvious remedy would be not an added expense but actually a great financial advantage to the mine by reason of the increased efficiency."

The principle advocated throughout the paper of throwing maximum responsibility upon the shoulders of the shift bosses does not meet with general approval. Under present systems it is, as a rule, possible for the energetic shift boss only to visit all the working places under his control once a day in accordance with the demands of the mines and works regulations. It is consequently necessary to rely upon the gangers in direct charge of the hammer "boys" or the machinememen to see that the requirements of safety are properly observed. These latter alone can see that the Kafirs do not drill into sockets or mistired holes, or commence work under dangerous hanging—for in the majority of places the day's work must necessarily be far advanced before the mine official puts in an appearance. The mine captain or shift boss should, of course, be responsible for the employment of men capable of judging these matters and should ascertain as far as possible that the proper precautions are taken, but it is unreasonable to expect shift bosses, with duties as falling to them at present, to make the initial inspections themselves before the commencement of work. Mr. Fergusson apparently opposed his own arguments when he urged that "the safety of a mine depends, from hour to hour, it might be said almost from minute to minute, upon the care and attention bestowed upon every portion of it by the mine officials." It is true that much reliance cannot be placed upon the perspicuity of the Kafir laborers—though often very trustworthy judges of their personal security—but it is too much to hope that a sufficiently large staff of mine officials can be provided for our large mines, with workings stretching for half a mile or more along the strike of reef and on many levels to relieve the individual worker from the responsibility of protecting his "boys," or even his fellows from danger. There is already too great a tendency to make the Rand miner an automaton and to rob him of all opportunities of doing good work as a thinking man of independent responsibilities.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alaska

NOME

The fleet of steamers from Seattle reached here earlier than last year, reporting less ice than in previous years.

VALDEZ

An automobile stage service for the benefit of mining interests between Valdez and the Summit, 30 miles distant, via the Valdez-Fairbanks wagon road will be inaugurated August 1. The cars will carry freight and passengers.

Arizona

GILA COUNTY

Superior & Boston—A battery of two 150-h.p. boilers, and a Nordberg hoist and compressor are being installed. The McGaw 3-compartment shaft is now 400 ft. deep, and is to be equipped with double-deck cages.

Old Dominion—The May production of copper is reported as 3,088,000 pounds.

Two Queens—In the Federal Court at Kansas City, Horn Brothers, Raymond P. May and S. H. Niger, were charged with using the mails to defraud in promoting the "Two Queens" group of mines at Wilhlem, Ariz. James B. Lynch of Philadelphia, produced letters, circulars and newspapers sent to him by the promoters. These stated that the mine was in operation and that ore was being shipped in paying quantities. Lynch bought 1100 shares of stock on representations made in the advertising matter.

J. H. Deaner, of Saginaw, Mich., testified that he bought stock on the installment plan, paying \$2 a month. District Attorney Van Valkenburgh offered as evidence a printed circular describing the mining property. Frank H. Horn, S. H. Snyder and Raymond P. May, were sentenced to serve a year and a day in the United States prison at Leavenworth and to pay a fine of \$500 each, while John E. Horn was fined \$500 in the Federal court. Appeal bonds in each case were filed.

GRAHAM COUNTY

Shannon—An important strike of ore was made recently at the Little Coronado on the 400-ft. level. A new 60-h.p. engine is to be installed.

Shannon-Arizona Railway—The directors of the company are Nathan L. Amster, E. B. Clough, both of Boston; John W. Bennie, R. D. Roberts and Jas.

A. Campbell, of Clifton. The company is capitalized at \$50,000 divided into 500 shares of par value \$100 each.

Detroit Copper—A flume has just been completed from the concentrator around Longfellow hill to the gulch southeast of Morenci. This is to take care of the tailings and prevent them from going into the San Francisco river. An oil-burning boiler of the Morenci smelter exploded last week. Five men were badly injured.

Messabi-Morenci Development Company—The directors of the company are Richard Lakenau, president; Dan Grant, vice-president; I. H. Knapp, secretary and treasurer; and C. E. Muir, all of Morenci. Hon. F. H. Hereford, of Tucson, is general counsel; Frank Rathbun, mining engineer; M. Danenhauer, of Clifton, is statutory agent.

County Road—The board of supervisors of Graham county has asked for bids for the construction of a public highway leading from East Clifton to Patterson's addition on the east side of the San Francisco river. Office at Solomonville.

Fumarole—The mine is being developed by the National Mining Exploration Company, of which F. A. Woodward is general manager.

California

SHASTA COUNTY

El Dorado—This mine, at Tower House, has been sold by Sherk Brothers to W. H. Roller. There is a small mill at the mine.

Mammoth—About \$50,000 worth of improvements will be made in July, in enlarging the blast furnace building and changing the converter crane.

SISKIYOU COUNTY

High Muck-a-Muck—The claims owned by Charles and Henry Herzog, near Etna Mills, are being opened. The railroad company opposed the patenting of the claims on the ground that they were not on mineral land, but the commissioner of the general land office has decided in favor of the Herzog brothers.

TRINITY COUNTY

Trinity River—This company, at Lewis-ton, has recently completed a long tunnel, and is now hauling in the heavy machinery for a hydraulic elevator.

TUOLUMNE COUNTY

The United Mines Corporation and Albany Pacific Mining Company have leased to E. N. Baker, of Cleveland, O., the Dead Horse, Eureka, Lady Washington, Golden West, California, Grizzly, New Albany and Mill Site. The lease is for 10 years and the lessee is to pay \$40,000 of debts on the properties.

Ralph—Operations will be resumed, the mine having been sold by the Baghdad-Chase Mining Company to San Francisco men.

Colorado

BOULDER COUNTY

Golden Message—A new hoisting plant is being installed on the property, near Sunshine, by Dr. Curtis Brown as trustee for the stockholders. A large body of milling ore is reported to have been opened.

John Jay—Under the direction of J. A. Bentley, of Denver, the mill near Jamestown will be overhauled. A roaster is to be installed and cyanide tanks added.

CLEAR CREEK COUNTY

Columbia and Eureka—Chicago people have become interested in this property, and are planning extensive development. Manager E. J. Butts, Georgetown, Colo., will later make arrangements for the installation of machinery.

Philadelphia—This company has leased the Dover-Brighton mill on Fall river and will start milling during the coming week. J. W. Boyd, Idaho Springs, Colo., is manager.

Lamartine—The dump has been leased by Oxley & Noonan, Idaho Springs, Colo., and will be hauled to the Jackson concentrating mill at Idaho Springs for treatment. There is estimated to be 50,000 tons in the dump.

Josephine—It is reported that electric drills are to be installed at this property. L. W. Partridge, manager, Georgetown, Colo.

Astor-Stewart—The company will install an air compressor and drills for use in its Scepter tunnel on Democrat mountain near Georgetown.

GILPIN COUNTY

Pine Cone—E. Shoush, of Macon, Mo., has taken a lease on this property near Black Hawk, Colo., and will install machinery.

Evergreen Gold and Copper—Manager Etienne A. Ritter, of Colorado Springs,

is having an 80-h.p. boiler installed in the mill which is to be overhauled to handle the dump and determine the treatment for the bornite ores. The property is situated in the Pine creek district.

Decatur—The company holdings in Moon gulch were sold this week at sheriff's sale to satisfy a judgment of \$4325. Decatur, Ill., people are interested and it is understood that they will reorganize and carry on active development on the property, near Rollinsville, Colo.

Sea Bird—Oklahoma people have become interested in this group in the Pine district and it is reported that machinery is to be installed. G. W. Hines, Rollinsville, Colo., is to be in charge.

Hazley-Gardner—William Dickerson, of Bald Mountain, Colo., has started work at this property in the Nevada district; the machinery is being overhauled and arrangements made for active developments.

Aurora—A deed has been recorded conveying from E. E. Clark to H. G. Shuck this claim in the Russell district for \$16,000. Pittsburg people are reported to be the new purchasers. P. R. Alsdorf, Central City, Colo., will be superintendent.

A. K. R.—Decatur, Ill., people interested in the Smuggler mine have opened up between 5 and 6 ft. of ore in the lower workings which is running high by amalgamation and the concentrates carry much better than average values. The Smuggler retort gold sells to the Denver mint at \$19.50 to \$19.80 per oz. The company during the past week has purchased claims adjoining their own, giving them 3000 ft. on the line of the Smuggler vein. G. M. Ashmore, Rollinsville, Colo., is manager.

Pearl Tatum—A 5-drill Rand compound compressor is being installed at the Sleepy Hollow mine, and deeper development will follow. Floyd Weed, Black Hawk, Colo., is superintendent.

Cashier—This company controlling the Pittsburg-Meeker mine is figuring on the installation of an electric compressor and pumps. W. Auger, Central City, Colo., is superintendent.

Gladstone—Eastern people are reported to have assumed control and E. H. Crabtree, Central City, Colo., is to have charge of this mine.

Penobscot—This company contemplates adding another compressor plant for driving their tunnel. P. J. Hamble, Rollinsville, Colo., is manager.

LAKE COUNTY—LEADVILLE

Birdella—The breast of the tunnel is in 400 ft., and another 100 ft. is to be driven to cut the President vein.

Pyrency—After several mishaps the pumps are again at work and the unwatering of the lower levels is only a question of a few weeks. The company, in unwatering the lower levels, is also draining the Greenback and the Mahala.

SUMMIT COUNTY

Robinson—At this old mine, at the town of Robinson, a 150-ton concentrating plant will be installed. The usual concentrating machinery, such as tables, jigs, etc., will be employed; also magnetic separators. The work is in charge of O. H. Fairchild, mining and metallurgical engineer, 202 Exchange building, Denver, Colo.

Indiana

GREENE COUNTY

The Pea Fry mine has made a contract with a large steel concern at Gary to take the output of the mine for the entire summer season. This will give steady employment to about 200 men.

SULLIVAN COUNTY

Keystone—The fire which started four weeks ago is still burning, but is being gradually smothered and within a week or 10 days is expected to be out entirely. The fire does not interfere with work in any other part of the mine.

VERMILLION COUNTY

Deering—Falling slate in Deering mine No. 8, in the Clinton field, killed two Polish miners on June 13. As the result of a visit by mine inspectors, Joseph Robinson, mine boss and George Kyle a shooter in the same mine No. 8, paid fines for violating the mining laws. Robinson was charged with failing to provide a separate current of air for each 50 men, and Kyle pleaded guilty to having "drilled on the solid," this term referring to the practice of making the hole into the coal deeper than the distance undermined by the machines.

Kansas

ZINC-LEAD DISTRICT

A tract known as the Happy Hollow mining land, southeast of Galena, has just been sold by Rains Brothers to Decker & Co., of Joplin, who will take up the work of developing the land at once.

Michigan

COPPER

Michigan—Over 300 ft. of drifting has been done in the adit on the Bee tract and about half the distance high-grade rock was exposed. This lode has also been cut by means of crosscuts from the "C" shaft, which is 650 ft. east of the adit opening. This lode has also been exposed at the 0th and 11th levels and at these points it was found richer than at the level above. The openings throughout are of a most encouraging nature. At the 17th level of the "A" shaft a cross-cut was driven to cut the Calico lode and at the point of intersection was found about 4 ft. wide and highly mineralized.

Tamarack—Rock shipments of about

350 tons daily are being made from No. 5 shaft to the Calumet & Hecla stamp mills. In this way a comparative test can be made on the character of the rock, stamping methods, and tailing losses.

Wyandot—Drifting has been started on the recently opened copper-bearing formation. This lode carries but a small amount of copper. Its further opening will be awaited with interest.

Osceola—This company continues to maintain its increased production. During the month of May about 122,000 tons of rock were stamped, yielding nearly 2,622,000 lb. of mineral.

Allouez—No. 2 shaft of this company is now sinking on the formation. This shaft was put down about 2300 ft. through barren ground before the vein was encountered. Work on the two-head addition of the stamp mill, which is owned jointly by this and the Centennial is nearing completion.

New Arcadian—Robert H. Shields, president, has returned from a visit to the east, and while there perfected all the details in connection with the transfer of the Arcadian to the new company. Active operations are to start about July 1. This company owns 3200 acres of land in the mineral zone, and a complete equipment. The old shaft is down about 200 ft., and will be reopened. A drilling outfit will be rigged up at the bottom to ascertain the condition of the formation at depth. The tract will be thoroughly prospected by drilling.

Astec—A meeting will be held early next month, when plans will be formulated for the beginning of active exploratory work. This tract contains 320 acres located between the Adventure and Lake properties.

IRON—GOGEBIC RANGE

Colby—Work has been suspended at this mine and the Ironton, near Bessemer, both owned by Corrigan, McKinney & Co. It is said that trouble with the local authorities about taxation is the cause.

Coppo—The Whiteside Exploration Company is drilling at this old mine and on the adjoining lands, near Marenisco.

IRON—MARQUETTE RANGE

Volunteer—This mine in the Cascade district is being thoroughly tested by drill.

MENOMINEE RANGE

Baker—Development is well advanced, and some shipments will be made this year from this mine, which is at the western end of the range.

Channing Gibbs—This property at Red Rock, near Amasa, is approaching the production stage, and a half-mile spur is being built to connect with the Chicago, Milwaukee & St. Paul road.

Stansbaugh District—Testing work and drilling are being carried out on several

forties by the Cleveland-Cliffs Iron Company. The Buffalo & Susquehanna Company is reopening the old Chicago mine and sinking the shaft 200 ft. deeper.

Minnesota

IRON—CUYUNA RANGE

Much exploration is going on this season, and it is hoped that the value of some of the properties will be definitely established. So far, the interest in the range has been largely of a speculative kind.

Interstate Mining Company—This company has been adding considerably to its holdings on the range. It is controlled by the Jones & Laughlin Steel Company.

IRON—VERMILLION RANGE

Section 30—Active work on this property is being carried on under direction of George A. St. Clair and Alfred Merritt, of Duluth. The showing is very good in No. 1 shaft which is now down 700 ft. In No. 2 good hard bessemer ore has been found.

Missouri

HOWELL COUNTY

Carson—The Frisco Ore Mining Company has abandoned this mine. The machinery is being torn down and a portion of it shipped to St. Louis. The mine has been operated by this company for seven years, and during that time about 3000 cars of ore have been shipped to the St. Louis Blast Furnace Company.

JOPLIN ZINC-LEAD DISTRICT

The large area of disseminated ore ground west of Joplin is now assured of four more mills. Much drill work is being done. Three large mining properties were recently sold at handsome figures. The Elking, north of Webb City, for \$100,000; the Keystone, south of Webb City and High-grade mine at Central City, price not stated.

Big Fly—The erection of this mill on the lease of the Louisville Lead and Zinc Company, of Joplin, just west of Chitwood camp, is proceeding rapidly and the building is almost completed.

Barefoot—This Joplin company is taking out a good tonnage of rich ore from the old Cardinal ground at the Midway tract.

Kalitan—R. K. Pitkin has sold his control of this company to John T. Robertson, of Joplin.

Knights Station—Four exceptionally rich zinc prospects have been drilled at depths ranging from 125 to 185 feet.

On adjoining land, to the West, there has been developed one of the greatest silicate prospects ever seen in the southwest. The ore is found under the surface at about 4 ft. The earth is removed with scrapers and the silicate is blasted out as one would blast limestone from a ledge.

Maltese Lead and Zinc Company—This Joplin company will begin operations west of Joplin in the Central City district.

Midnight—Dr. George E. Ladd, of Wilburton, Okla., is making arrangements to resume operations on his property at Zincite. A 5-in. steam pump was installed recently.

Lone Star—Articles of incorporation were filed at Carthage. The company owns mining property near Knights' station. C. J. Tobins, of Carthage, is one of the principal owners.

Integrity—Work has begun on a 250-ton milling plant to take the place of the one destroyed by fire last year.

O.K.—After a shutdown of 5 months, the mill began operations last week. The mill has been remodeled, and has a capacity of 100 tons daily.

Sampson—The mill is to be operated by electric power, and has a capacity of 250 tons per day. It is a new plant and will begin treating ore soon.

Herald—The 300-ton plant resumed operations June 18.

Montana

BUTTE DISTRICT

Amalgamated—At the Pennsylvania mine an air shaft has been constructed down to the 1600-ft. level and has materially improved the ventilation. At the 1200-ft. level in the air shaft a blower with a capacity of 60,000 cu.ft. per minute forces the air downward. The shaft is now down 1800 ft. and the principal work is being done on the 1400-, 1600- and 1800-ft. levels. Between 1000 and 1200 tons are being hoisted daily. At the Mountain View mine a 400-gal. electric pump has been installed. On the 1200-ft. level of the Leonard mine two Nordberg pumps with a capacity of 600 gal. each are in use. At the Badger State mine sinking on the shaft has been resumed. The shaft at present is 1200 ft. deep and will be sunk to the 2000-ft. mark. At the Red Bowler mine the shaft is now being sunk from the 300- to the 600-ft. level. Those in charge of the Amalgamated properties in Butte state that its operating companies, together with the North Butte, are producing at the rate of 14,000 tons of ore daily. Of this amount the Washoe smelter, at Anaconda, treats 10,000 tons and the Boston & Montana smelter at Great Falls treats 4000.

JEFFERSON COUNTY

Alta Montana—C. C. Titus, formerly superintendent of the independent smelter at Ponderay, Idaho, has been placed in charge of the work at the Alta mine.

Assets Gold Mining Company—The company has recently been incorporated under the laws of Montana with a capital stock of \$3,000,000, with 600,000 shares of the par value of \$5. The incorporators are W. W. Barr, of Seattle, George

Northup, of Grand Rapids, Mich., and James A. Barr, of Houghton, Mich. The company will operate the Farlow group of claims situated four miles from Jefferson City.

LEWIS AND CLARKE COUNTY

Gold Crown—The new 80-ton mill has been put in operation under the direction of W. J. Heiber. The mill is thoroughly equipped with a Blake crusher, Fraser & Chalmers rolls, revolving screen, hydraulic classifier, six-compartment jig, elevators, Wilfley tables, a 70-h.p. boiler and 50-h.p. Atlas engine. The main shaft is down 250 feet.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Florence Goldfield—A new discovery of high-grade ore was made last week on the Engineer's vein on the fourth level from the main shaft. The foundations are under way for the extension to be added to the mill. The tube mill and extra tables are expected about July 1, which will increase the capacity to about 175 tons per day. The old Reilly Lease workings are now being put in shape for production of ore. At the meeting held in Denver June 7, a dividend of 10c. per share, amounting to \$105,000 was declared.

Nancy Donaldson—A hoist is being installed on this Red Mountain property, about eight miles northeast of Goldfield. The property, consisting of four claims, is managed by J. C. MacCormack, of Goldfield, and the work will be in charge of John T. Hawkins, who is also manager of the James Burns interests in Goldfield.

ESMERALDA COUNTY—LUCKY BOY

Mitchell Fairfield Lease—A 100-h.p. hoist and 10-drill compressor are being installed on this property. The shaft is now 200 ft. deep and shows ore of a good grade.

Hubbard Lease—About 70 tons of ore are being shipped daily. The lease has less than 60 days to run.

ESMERALDA COUNTY—RAWHIDE

Rawhide Queen—The Grunt Balloon lease recently struck good ore on the 185-ft. level. The ledge is 7 ft. in width, and will average about \$48 in gold per ton. This is the best strike that has been found in the camp.

Original Rawhide—The Kerns No. 1 lease on the Queen Estate has struck ore on the 150-ft. level, assaying \$18 to \$20 per ton. Not enough work has been done to determine the size and value of the strike.

Rawhide Coalition—The Coalition Crown lease is now installing a 12 h.p. hoist and a 40-ft. galloways frame. The shaft is down about 90 feet.

Borward Seavastika—Extensive operations on the Buckskin group of claims will

begin soon. The property is about 22 miles south of Rawhide. The main office is at 181 La Salle street, Chicago.

LINCOLN COUNTY

Alunite—It is reported that the Alunite Mining Company has purchased three fractional claims from "Jack" Hayes and associates. The price is said to be \$25,000.

LYON COUNTY—YERINGTON

Wabaska Copper—Recent development work on the 500-ft. level of this property has disclosed promising orebodies, the copper content being in excess of 3 per cent. The property is to be equipped with a compressor, pump and larger hoist, and it is reported that the company intends building a smelter.

NYE COUNTY—BONNIE CLARE

Bonnie Clare—This recently reorganized company is leasing its mining properties and for the present will operate the mill only on company account, working over the tailings of which there are about 4000 tons. Later a tube mill and additional concentrators will be added and the mill operated as a custom mill. A. J. Trumbo, of Bonnie Clare, is in charge of the work.

NYE COUNTY—BULLFROG

Montgomery-Shoshone—The final clean-up for the month of May showed a production of \$50,000. At present the mill is treating between 200 and 220 tons of ore per day. Approximately 5000 tons of good milling ore have been developed on the 500-ft. level. The stope on the 300-ft. level is 100 ft. long and 12 ft. wide.

National Bank—J. C. Kennedy and others have secured a two years' lease on this property, and intend to push development work as fast as possible.

Mayflower—The output for May was \$10,700, from 390 tons of ore treated. A saving of 92 per cent. was made. The ore is from the stope between the 200- and 300-ft. levels.

Rickard-Garburg Lease—Ore of a high shipping grade was broken into last week in the winze 15 ft. below the tunnel level. The ledge shows from 4 to 5 ft. in width. Average samples taken across the entire vein return values from \$50 to \$200 per ton. A shipment comprising about 30 tons is sacked and will be sent out this week. The main shaft is being pushed down by three shifts, and a crosscut will be run to cut the ledge at the 200-ft. level.

Trumps Consolidated—A carload shipment from the Jingles & Clothier lease, valued at \$25 per ton was made last week, to the smelter at Needles.

Bullfrog Pioneer—Shipments from this property are now being made at the average of 75 tons per day. A car of high-grade ore was shipped last week, which netted the company in excess of \$10,000 for the car. The entire product of the

mine is being handled by the Western Ore Purchasing Company.

NYE COUNTY—TONOPAH

Belmont—The old Belmont shaft has been unwatered and preparations are now being made to connect with the east crosscut on the 1000-ft. level, 450 ft. below. A hole 6 or 8 in. in diameter will first be made with a churn drill to afford better ventilation in the work of raising the three-compartment shaft from the 1000-ft. level. Extremely good-grade ore 4 ft. thick has been exposed on the 1000-ft. level.

MacNamara—A new body of high-grade shipping ore was opened last week in the winze from the west drift on the 200-ft. level. The vein is 6 ft. wide and of shipping grade across its entire width. The new compressor which is to be installed should reach the mine about June 25.

Tonopah Mining—A less amount of development work than usual is now being performed, due to the lack of compressor capacity. The shaft is still being sunk, and is now below the 1400-ft. point. The month of May showed the best record ever made at the mill, 14,480 tons of ore being crushed which returned over \$230,000 in bullion and \$50,000 in concentrates.

New Mexico

SOCORRO COUNTY

Top Development Company—The Top Mining Company has been reorganized into a development company, capitalized at \$650,000. The property is in the Mogollon district. E. A. Wayne is principal stockholder.

Oklahoma

There will be an investigation conducted during the summer on the mineral resources of Oklahoma by the Oklahoma Geological Survey. The plans now developed will consist largely in the investigation of portland cement and clay products in the northern and eastern parts of the State, and a study of the asphalt deposits in several of the southern counties. Prof. D. W. Ohren, L. L. Hutchinson and Ben C. Bolt will have charge of the field-work.

Oregon

LANE COUNTY

West Coast—The clean-up made June 1, after six days' run resulted in obtaining \$2500. Superintendent Ryan states that the mill will be closed down for a short time in order to make some necessary adjustments and improve the ore-transportation system.

Mayflower—W. P. Ely, of Kelso, manager, reports that the mill was started May 1, and that he expects to put 500 tons of ore through, as a trial run, using

the cyanide process. This is the first cyaniding done in the Bohemia district.

Combination—Rich silver ore has been discovered in one of the lower tunnels. Milling operations will begin soon and the concentrates will be shipped to the Tacoma smelter.

Pennsylvania

ANTHRACITE COAL

Ferndale Colliery—This colliery is to be closed down in consequence of a decision recently rendered. The miners at the colliery, which is owned by the Hill-side Coal and Iron Company—the Erie railroad—appealed to the Board of Conciliation, their complaint being that the company was not paying sufficient wages for rock work. The board after hearing the case decided against the company and held that the price for rock work should be \$2.20 per yd. The company, of course, accepted this decision and paid the men at that rate up to date, but decided to close down the mine on the ground that it was too expensive to work. This is said to be the first case since the Board of Conciliation was appointed in 1903, when one of its decisions resulted in closing a colliery.

Kingston Coal Company—The new coal breaker No. 2 of this company last week passed all records for a day's work. In one day 1410 cars were raised through the shaft and slope and all the coal passed through the breaker, making a total of 4300 tons over the screen. The breaker was recently overhauled and rebuilt, being furnished with all the latest improvements, such as spiral conveyers, Emery slate pickers and others. The work was done under the direction of F. E. Zerby, general manager of the company.

BITUMINOUS COAL

Pittsburg Terminal—All the coal mines in the Pittsburg district along the West Side Belt railroad, which belong to the Gould interests and which were formerly operated by the Pittsburg Coal Company, have been placed in operation under the management of the Pittsburg Terminal Railroad and Coal Company. The mines have been idle for some weeks, during which time new machinery for loading cars has been installed, and other improvements to facilitate the handling of coal over the Wabash lines were made. B. F. Bush, receiver of the Western Maryland railroad, is president and J. J. Keefer, formerly general manager of mines of the Monongahela River Consolidated Company, is vice president and general manager in charge of operation.

The 500 steel hopper cars ordered some time ago by the Wabash-Pittsburg Terminal railroad are being delivered at the rate of 25 per day by the Standard Steel Car Company, and a large number of them have been placed in service to handle the output of the West Side Belt mines.

Utah

BEAVER COUNTRY

Cupric Mines—The shaft has been penetrating bunches of copper ore for some time but at a depth of about 300 ft. the ore showing became more favorable and has continued to improve as the work progressed. L. Morris, general manager, Beaver, Utah.

Cave—A car of copper ore was recently marketed, averaging 17.5 per cent. copper. The management now plans to ship copper ore regularly and to take out at least one car of iron ore per day.

JUAB COUNTY

East Tintic—The latest strike made in the Ralph claim of this company is in the shaft at a depth of 314 ft. At that point 14 in. of high-grade silver ore has been cut. It is of different character from that which has been opened in the cave 60 ft. farther east; it is quartz ore running lower in lead but higher in silver content than the cave ore.

SALT LAKE COUNTY

Utah Copper—The record output at the Utah Copper mine at Bingham was made on June 13. On this day this company handled the greatest tonnage of ore in its history. During the day 249 cars of 55-ton capacity amounting to 13,700 tons of ore left the mine for the mill at Garfield.

Ohio Copper—The first section in the new mill of the Ohio Copper will be ready to go into commission in about two weeks but it is probable that the management will defer operation until the mill is sufficiently completed to treat 3000 tons of ore per day. This would only be about two months longer and in that time the mine could be completely opened down to the 1400-ft. or Mascotte-tunnel level and a large and steady output easily maintained.

TOOELE COUNTY

Western Utah Copper—Superintendent J. E. Bergh reports having driving 100-ft. on the 300-ft. level since operations were taken up at that point. Work has also been started on the 600-ft. level.

Washington

FERRY COUNTY

Blacktail—The fourth car of ore was shipped to the Tacoma smelter last week.

SKAGIT COUNTY

Anacortes—T. F. Thomas, Ballard, Wash., and associates of Seattle have purchased a tale mine from Thomas Sharp, seven miles west of Anacortes for \$75,000, the first payment of \$10,000 having been made, the balance to be paid in monthly installments.

Wisconsin

ZINC-LEAD DISTRICT—PLATTEVILLE

A company of 30 shareholders has been formed to drill for lead and jack on the Weigle and Billmeyer tracts southwest of the Klar-Piquette.

Badger—The Galena Iron Works have contracted to construct a small milling plant for this company four miles southwest of Dodgeville; Geo. Lindsey, of Dodgeville, is in charge of the mine.

Dark Horse—A 50-ton mill is to be put up.

Ellsworth—W. N. Smith, of Platteville, has purchased the Empress mill for removal to this mine, at Livingston.

Optimo—Foundations are being laid for a 50-ton mill at this mine, at Linden; Jas. Billingsly, of Galena, Ill., is general manager.

Wisconsin—A new shaft is being sunk on the Longhenry land by The Wisconsin Zinc Company. This company has obtained options on the Kennedy mine, at Hazel Green, and the Pittsburg-Benton, at Benton.

Weigle—This has been re-organized as the Standard Zinc Company, and a force of men put to work at the mine.

Canada

BRITISH COLUMBIA—QUEEN CHARLOTTE ISLANDS

Small quantities of placer gold are being recovered by miners working on the east coast of Graham island.

Preparations are being made to take in a diamond drill to prospect coal measures occurring in the Yakoun district of Graham island.

A 2-ft. vein of gold quartz is being prospected on the Gold Harbor claim, west coast of Moresby island.

BRITISH COLUMBIA—ROSSLAND

Consolidated Mining and Smelting Company—Another copper furnace, described as the largest in Canada, has been blown in at Trail. There are now four copper furnaces at these works, having a total treatment capacity of about 1800 tons of Rossland ore per day.

Le Roi No. 2—For the purpose of developing the extension of one of Le Roi lodes, which dips into the Annie claim of Le Roi No. 2 group, a shaft is to be deepened from 900 to 1200 ft. Present dimensions of the shaft—6x16 ft.—will be maintained to the 1200-ft. level. It is estimated the cost of the work will be about \$18,000 and that it will take eight months.

QUEBEC

Two distinct booms are in progress in the southern part of the Province. One is in asbestos, and is largely due to the formation of the Amalgamated Asbestos

Company. Property in the asbestos district—and anywhere near it—is held at high figures, in some cases out of all season.

The other boom is in placer gold in the Beauce and Compton districts, where placer mining on a very small scale has been carried on for years, but there has never been any production of importance.

Compton Gold Dredging Company—This company's agents having failed to come up to their agreement to provide funds for a dredge by May 1, Kennedy & House, of Beebe, the owners, have demanded the surrender of the property.

Eastern Canada Mines Company—This company, it is stated, has arranged to sell the Chat Noir placer.

Eastern Canada Smelting Company—This company is sinking a shaft on the McDonald copper claim at Weedon, on which it has an option.

Mexico

CHIHUAHUA

Midland—D. M. Evans, manager, reports that development work is ongoing bodies of high-grade lead-silver ore.

Rio Plata—D. W. Shanks, general manager, reports an important strike in the Santa Barbara mine. Only 15 out of 25 stamps are in operation, due to lack of water.

San Toy—The management announces that the balance of the floating debt has been paid. The amount of this debt, Jan. 1, was \$215,653. The funds for this came from the net profits on the ore sold since that date.

MEXICO

Mexico Mines of El Oro—Report for May: Mill ran 22 days and crushed 7334 tons of ore, yielding bullion valued at \$100,760; working expenses \$32,990; development \$5000; net profit of \$60,870.

El Oro—Report for May: Mill No. 1 ran 25 days and mill No. 2 operated 23 days, crushing 20,927 tons of ore, yielding bullion valued at \$186,480; working expenses, \$100,020; development \$22,600; net profit \$63,860; profit on railway \$6000; expenditure on permanent improvements \$7000.

SONORA

Greene-Cananea—A concession has been granted for building a railroad from Imuris, on the Sonora railway, east, through northern Sonora, to a point on the Mexican Central in Chihuahua. Chas. S. Henning, with an office at Douglas, Ariz., is chief engineer.

Australia

VICTORIA

The gold production for the five months ended May 31 is reported at 268,000 oz. fine, or \$5,558,340 in value.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, June 23—The bituminous coal trade in the East continues to show an improvement which is not marked, but rather steady. Steam coal is in better demand, which indicates an improvement in business generally.

The anthracite trade is a little more active than it has been, and most of the companies are running their collieries at a nearer approach to full time.

Fair reports come from the trade in the West. Steam coal is in better demand and the large consuming centers are calling for more shipments. In part, perhaps, this is a result of the recent policy of keeping shipments down closely to avoid demurrage sales, but in part it is due to a real increase in demand.

The Lake trade is looking up and shipments have been increasing. Up to this date they are considerably above those of last year; sufficiently so to promise a good season total.

Tariff on Coal—Much interest is taken in the question of the tariff on coal, and especially on the question of a reciprocal arrangement with Canada. Many Pennsylvania shippers favor such an arrangement because they have a large trade with Canada; but West Virginia men are opposed because they are cultivating the New England trade and do not want to come into competition with Nova Scotia coal. A similar local division of opinion exists in Canada itself. Nova Scotia miners are opposed to reciprocity, fearing to lose Canadian trade; Ontario favors it as a means of getting cheaper coal; while British Columbia also favors it owing to its large trade on the Pacific Coast.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, up to June 12, short tons:

	1908.	1909.	Change.
Anthracite.....	2,469,413	2,347,762	D. 121,651
Bituminous.....	14,419,474	16,613,741	I. 1,194,267
Coke.....	3,051,632	4,444,043	I. 1,392,411

Total.....19,940,519 22,405,546 I. 2,465,027

Increase for the week, 117,610 tons. Total increase year to date, 12.4 per cent.

Coal tonnage passing the locks on the Monongahela river, four months ended April 30, was 2,584,820 short tons in 1908, and 3,206,720 in 1909; an increase of 621,900 tons.

Coal passing Davis island dam on the Ohio, four months ended April 30 was 961,215 short tons in 1908, and 1,756,345 in 1909; increase, 795,130 tons.

Coal receipts at St. Louis, four months ended April 30 were 2,374,541 short tons in 1908, and 2,267,188 in 1909; decrease, 107,353 tons.

Coal shipments by water from Seattle and Tacoma, Wash., four months ended April 30, were 212,180 tons in 1908, and 95,554 in 1909; decrease 116,626 tons. These shipments are mainly to California and Alaska.

Bituminous coal and coke shipments, Pennsylvania and West Virginia, four months ended April 30, short tons:

	Coal.	Coke.	Total.
Balt. & Ohio.....	6,434,050	1,302,873	7,736,923
Buff. & Roch. & Pitta.	1,849,644	147,557	1,997,201
Buff. & Susquehanna	484,838	107,161	591,999

Total.....	10,062,896	315,331	10,378,227
Total, 1907-08.....	8,957,603	295,513	9,253,116

Deliveries this year to points west of mines, 4,987,388 tons coal and 179,400 coke; points east, 1,278,800 tons coal and 135,931 coke; tidewater, 3,606,317 tons coal; anthracite to line points, 7593 tons.

New York

ANTHRACITE

June 23—The anthracite trade is looking up and business has been rather more active. This is partly to be explained by the approach of another 10c. rise which will be due next week. The Reading

company is reported to be running all its collieries five days during the week, and some other companies are running on full time.

Until July 1 there will be no change in prices. We quote for prepared sizes, \$4.45 for lump, and \$4.70 for egg, stove and chestnut, all f.o.b. New York harbor. For steam sizes current quotations are unchanged at \$3.10@3.25 for pea, \$2.35@2.50 for buckwheat, \$1.70@2 for rice or buckwheat No. 2, and \$1.25@1.50 for barley, f.o.b. New York harbor points.

BITUMINOUS

A little more interest has been shown in the market, notwithstanding the general hot weather of the week. Manufacturers are evidently needing more coal and are beginning to think of laying in winter stocks, especially in the far Eastern ports. Inquiries from that section are coming in and the Sound is also buying more coal. New York harbor continues a weak spot, but matters are looking up even there. Prices remain the same at \$2.40@2.50, f.o.b. harbor shipping port, for lower grades and \$2.60 up for better coal. All-rail trade is improving a little. Cars are plenty, but transportation still rather slow.

The English coal troubles are still attracting attention. The recent sharp advance on export coal at Cardiff, it is thought, may be the means of throwing some South American trade this way, and some shippers are negotiating for vessels to be ready for such a movement.

In the Coastwise trade vessels are still in good supply and there is little or no change in rates. From New York cargoes are taken at 60@65c. to points around Cape Cod.

Birmingham

June 21—Coal mining in Alabama shows improved conditions and the output is better than it has been for some time, with a steady demand coming in. Recent orders placed indicate that consumers are looking this way for their needs. The Central of Georgia railroad will need something like 80,000 tons of coal from this section between now and the end of the year.

Chicago

June 21—Buying of steam coals continues quiet but steady; the summer demand for fine coals makes itself strongly felt, and lump from Illinois and Indiana

names is very weak. Domestic buying is very light. Shipments of western lump to this market are too large and should be curtailed. Eastern coals are again too plentiful and show old-time conditions of demoralization of prices to escape demurrage charges. Competition is keen for any good order of either eastern or western, with the result of further lowering of prices. The summer business, it should be borne in mind by shippers and prospective shippers, is in this market essentially of fine coals.

Illinois and Indiana lump, when it sells, brings \$1.75@2.15; run-of-mine, \$1.60@1.75 and screenings, \$1.50@1.70. Contract sales of these coals are at low figures and some new contracts are made at still lower prices, especially on run-of-mine.

Of coals from east of Indiana smokeless is 15 or 25c. off from circular prices, selling for \$3.05@3.30 for lump and \$2.75@2.95 for run-of-mine. Bocking is 10 to 25c. off the circular price of \$3.15; Pittsburg No. 8 and Youghiogheny have a light open market at \$2.05 and \$3, respectively, for 34-in. lump.

The anthracite market is dull and even the approach of the end of June with the less discount for July fails to stir activity.

Cleveland

June 22—Trade is steady, and the demand for steam fuel, chiefly slack, is improving. The quotations for Middle district coal are: Lump, \$1.85@2; run-of-mine, \$1.65@1.75; slack, \$1.25@1.35. For No. 8 district lump, \$1.00@2.05; run-of-mine, \$1.70@1.80; slack, \$1.40, all f.o.b. Cleveland. A circular just issued puts prices of Massillon coal for domestic use at \$2 for lump and washed nut; \$1.85 for run of mine and \$1.75 for slack, all f.o.b. mines; these prices to hold until Aug. 31 next.

Indianapolis

The tendency is still toward improvement and the mining conditions have developed satisfactorily during the past week. While the coal prices are not attractive, the future indications seem to promise much. The present prospect for work at the Indiana mines in general is better than it has been for several years. This condition extends over nearly all the State. The Gary Steel Works are contracting for much coal.

Pittsburg

June 22—Coal production continues at fairly steady gait, and preparations are being made for the general resumption of Lake shipments after July 4. The market is not very active. Nominal prices remain at \$1.10 to manufacturers and \$1.20 to retail dealers, for mine-run at the mines, these prices being shaded 5 to 10c. Slack is quoted at 10 to 15c. per ton.

Connellsville Coke—The appraisements in connection with the proposed merger of

independent operations will be completed this week. A formal announcement of the properties to be included and the identity of the backers is promised for about July 15. It is admitted that some of the high-priced properties may be dropped, but the claim is, nevertheless, made that two-thirds of the independent acreage in the Connellsville field will be merged.

The market shows a slightly firmer tone, some operators having advanced prices, but the market, as a whole, can hardly be quoted more than 5c. a ton higher on furnace coke. Furnace coke, prompt, is \$1.55@1.60; contract, \$1.65@1.75; foundry, prompt, \$1.80@2; contract, \$1.90@2.25.

The *Courier* reports the production in the Connellsville and lower Connellsville region in the week ending June 12 at 299,486 tons, an increase of 8500 tons over the previous week; shipments as 4138 cars to Pittsburg, 6213 cars to points west of Pittsburg and 730 cars to points east of Connellsville, a total of 11,081 cars, an increase of 900 cars.

Foreign Coal Trade

German Coal Trade—Imports and exports of fuel in Germany, four months ended April 30, metric tons:

Imports:	1908.	1909.	Changes.
Coal.....	3,360,489	2,992,131	D. 368,358
Brown coal.....	2,377,592	2,583,140	D. 394,852
Coke.....	109,181	207,866	I. 97,785
Briquets.....	62,693	61,292	D. 1,401
Exports:			
Coal.....	6,367,242	6,934,991	I. 567,749
Brown coal.....	7,903	9,542	I. 1,639
Coke.....	1,136,219	1,099,710	D. 36,509
Briquets.....	548,701	442,737	D. 105,964

Coke exports this year included 8308 tons to the United States.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on June 12: Best Welsh steam, \$4.14; seconds, \$3.66; thirds, \$3.84; dry coals, \$4.08; best Monmouthshire, \$3.60; seconds, \$3.48; best small steam, \$2.70; second, \$2.58. All per long ton, f.o.b. shipping port. There has been a sharp advance, ranging from 12 to 24c. per ton.

Iron Trade Review

New York, June 23—Business in the iron and steel markets continues fairly active, especially when it is considered that the month of July is approaching, when trade is usually slack. Orders continue to come in well—not quite with the rush that was evident in the latter part of May, but still on a fairly good scale; and it is noted that specifications on contracts are coming in regularly and freely. Most of the mills have no complaint to make.

In finished material structural steel continues to lead and the volume of small contracts reaches a large total. Only a few heavy contracts are pending at the present time, but more projects are com-

ing up and others will soon be in a position for tenders. It is noted that the fabricating companies are inclined to ask prices a little higher than they have been accepting. The railroads are still rather backward, although there is now considerable placing of bridge work and some orders for cars. The only heavy orders for rails have come from the Harriman lines. It is said that American makers have secured an order of 50,000 tons of rails for South America.

In pig-iron foundry orders have been inclined chiefly to moderate quantities. A few large contracts both for foundry and basic has been placed for fourth-quarter delivery; most of them at a slight advance on current prices. Furnaces are inclined to be rather firm in their views of prices and to ask advances on all orders for future delivery.

Wage Increases—The Jones & Laughlin Steel Company, of Pittsburg, the Cambria Steel Company and Pennsylvania Steel Company on July 1 will restore wages to the rates prevailing before a 10 per cent. reduction was made last April. The same action will be taken by the Thomas Iron Company, one of the largest merchant-furnace interests, and by several less important companies.

Baltimore

June 22—Exports for the past week included 143,038 lb. zinc dross and 3,787,200 lb. steel billets to Liverpool. Included in imports were 6200 tons manganese ore from Vizagapatam, India.

Birmingham

June 21—Optimism prevails among the pig iron and steel manufacturers. The demand is equal to the output and the inquiries that are coming in are satisfactory. The sales are still in small lots with occasionally a large quantity. The quotations show but little change. No. 2 foundry is being held at \$11.50 per ton, delivery during the third quarter at the latest. Iron during the latter part of the year is being quoted at \$12 per ton with some tentative orders in hand. The make promises to be kept up. The Birmingham Coal and Iron Company announces that as soon as No. 2 furnace goes out of blast for repairs, No. 1 at Vanderbilt, will be started up.

The appointment of receivers for the Woodstock Iron Company, upon a petition filed in the United States court, in involuntary bankruptcy, during the past week, promises to be temporary. J. M. Barr, president of the company, is one of the receivers and W. E. Leake the other.

Chicago

June 21—The iron market shows no signs of weakening so far as sales or prices of pig iron generally are concerned, and iron and steel products are increasing in demand week by week. Foundry iron

is still selling in small lots, with prices practically unchanged from last week. The demand for Northern iron seems to be increasing somewhat at \$16.50, generally quoted and obtained on fourth-quarter business. For Southern iron \$11.50, Birmingham (\$15.85, Chicago), is standard, with some interests very strong for 25 or 50c. more. Lake Superior charcoal is in good demand at \$19.50.

Aside from a few purchases of long-deferred requirements, the market continues to have transactions of only a few hundred tons each. The average consumer is buying, as heretofore, only a short time ahead, but continues also feeling the market with inquiries for good-sized amounts, with the expectation of rushing in quickly should a turn toward higher prices appear. With the heavy consumption of iron and steel that is beginning to appear, this attitude seems destined soon to disappear. That the number of small purchases is large and increasing shows generally diffused improvement in the melter's business.

Railroad supplies and structural material continue to lead the market for iron and steel goods, with other products in good and increasing demand. Coke is somewhat more active and firm at \$4.70, Chicago.

Cleveland.

June 22—The strike of lake seamen is making less trouble, and all the vessels needed are moving. The longshoremen voted against the proposed sympathetic strike. Ore is moving freely. Some sales are reported.

Pig Iron—A moderate business only has been done, chiefly in small lots, with one or two up to 5000 tons each. Prices are firm around \$15.25@15.50 for No. 2 foundry and \$15.75 for bessemer pig.

Finished Material—Several contracts for structural steel are reported, including one large one. Bars are quieter, most buyers being supplied for the present. Specifications on contracts are coming in well.

Philadelphia

June 23—The pig-iron market continues strong and sales foot up a pretty large total. Foundry-iron orders are not very large, but there has been considerable business in basic and quite a call for low-grade iron for pipe foundries. Sellers are pretty firm in their views and No. 2A foundry may be quoted at \$16.50@16.75; No. 2 plain, 50c. less. Gray forge is more active than it has been, around \$15.25. Some Virginia iron is selling, but not much Alabama.

Steel Billets—There is a better demand for small lots but no large sales. Advances are being asked and at least \$2 per ton more is wanted than a few weeks ago.

Bars—The market is stronger and mills are asking \$1 or \$2 more per ton for re-

fined iron, and \$1 more on steel bars. Store trade is improving considerably.

Sheets—A big business is being done in small orders for prompt shipment.

Scrap—Sales have not been large, but dealers are not regretting this. They are holding on to their piles, looking for a big profit soon. Heavy steel scrap is being gathered in wherever it can be found.

Pittsburg

June 22—Railroad buying continues to furnish the chief activity in the steel trade. The buying of steel cars by leading roads is on quite a liberal scale, while locomotives and track materials are being taken and rail orders are averaging a large tonnage. The largest single purchases are those of the Harriman lines, about 150,000 tons, while the Argentine order, 49,000 tons, is the best export rail order taken for some time.

While new buying of steel products by manufacturers and jobbers is on a reduced scale, orders and specifications on old contracts are on a liberal scale, and June will probably prove to be the record month of the half year. Specifications have been so liberal that some of the mills have gotten behind, and in extreme cases rolling schedules are being made up 30 days in advance.

Pig Iron—The market has continued to show an advancing tendency, and while prices are not quotably higher on all grades, there is a distinctly firmer tone in every direction, and some sales have been made at higher prices than formerly. Some small lots of foundry iron, for instance, have sold at \$15.25, Valley, for early delivery, while the minimum for such delivery is \$15, Valley, \$15.25 being demanded for delivery over the third quarter or second half, an advance of fully 25c. in the week. While basic might be obtained for early delivery at last week's quotation of \$14.75, Valley, the market is generally held to be \$15 for extended delivery. Bessemer is firm at \$15.25, Valley, and it is doubtful if much iron could be picked up at this price. Forge is quotable at \$14.15, Valley.

Steel—The scarcity of open-hearth steel has become more pronounced. Open-hearth billets are quoted at 50c. or \$1 above the nominal market of \$23, which still prevails on bessemer billets. Open-hearth sheet-bars are also scarce, being quoted at \$20, with bessemer at \$25. The nominal market is \$25.50, delivered, but this price was shaded a few weeks ago to \$24 or less. It is understood that these low-priced sales were of bessemer steel only, the sellers not being able to furnish open-hearth bars, and that the present scarcity of open-hearth is due to buying by consumers who must have a proportion of open-hearth, but covered on bessemer only. Plates are not as strong as structural shapes, and 1.25c. is occasionally done on attractive business, the regular

market being quotable at 1.30c., the same as on shapes.

Sheets—Demand has improved somewhat, and the market is slightly firmer. Capacity continues to be but indifferently employed, but this is almost a permanent feature of the sheet trade, since even in 1906 and 1907 there was frequently some idle capacity, while several new mills have been built since then, and there are further projects under consideration at the present time. The market can be quoted at 2.20c. for black and 3.20c. for galvanized, but occasionally on attractive business these prices are shaded \$1 per ton.

Ferromanganese—The market has shown a slightly firmer tone, although transactions are not large, and is quotable for early delivery at \$41, Baltimore, or \$42.95, Pittsburg; contracts for next year commanding about \$42, Baltimore.

Sault Ste. Marie Canal

The total freight passing through the Sault Ste. Marie canals for the season to June 1 is reported as follows, in short tons:

	1908.	1909.	Changes.
East-bound.....	1,049,313	3,845,433	1,279,120
West-bound.....	618,829	1,350,529	1,720,700

Total.....1,668,142 5,195,962 1,3,516,822

In 1907 the total was 8,022,877 tons. The number of vessel passages this year was 2130, giving an average cargo of 2434 tons. The mineral freights included in the totals were as follows, in short tons except salt, which is in barrels.

	1908.	1909.	Changes.
Coal.....	453,121	2,036,360	1,683,239
Iron ore.....	263,882	3,028,609	1,2,764,727
Pig and man. iron.....	60,620	55,000	1,41,880
Copper.....	14,264	21,613	1,7,349
Building stone.....		450	1,450
Salt, bulk.....	168,654	164,340	1,406

In 1908 ore traffic did not fairly begin until June. Iron ore formed \$8.4 per cent. of the total tonnage this year; coal, 21.2 per cent.

Metal Markets

New York, June 23—The metal markets have shown a tendency to recede rather than to advance; sales have not been so active, and there is less speculative business.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

	Metals.	Exports.	Imports.	Excess.
Gold:				
May 1909..	\$11,171,265	\$ 2,263,721	Exp. \$ 8,907,544	
" 1908..	26,555,913	3,101,092	Exp. 23,454,811	
Year 1909..	55,387,891	17,857,537	Exp. 37,530,354	
" 1908..	44,891,267	22,958,223	Exp. 21,933,044	
Silver:				
May 1909..	4,428,448	3,867,388	Exp. 571,060	
" 1908..	4,128,334	3,359,598	" 638,736	
Year 1909..	24,554,629	18,592,455	" 5,922,174	
" 1908..	21,077,185	17,088,150	" 3,889,035	

Exports from the port of New York, week ended June 19: Gold, \$50,000 to South America; silver, \$772,840, chiefly to London and Paris. Imports: Gold, \$95,418, from the West Indies and South America; silver, \$52,084, from the same countries.

Gold—The price on the open market in London was unchanged at 77s. 9d. per oz. for bars. The gold arriving went chiefly to the Bank of England. In New York exchange rates were high but no gold has been actually shipped to Europe.

Platinum—Business shows the usual summer quiet and prices are unchanged at \$22.50@23 per oz. for refined platinum, \$25 for good metal, and \$18@20 for scrap. The price of iridium has been raised and most dealers anticipate an advance in platinum.

Our special correspondent reports from St. Petersburg, under date of June 10, that sales have been a little better but this has had no influence on prices, which remain unchanged. Platinum is quoted at Ekaterinburg at 4.50@5 rubles per zolotnik for crude metal, 83 per cent.; and at St. Petersburg at 18,000@19,000 rubles per poood. These prices are equivalent to an average of \$17.11 and \$18.13 per oz. respectively.

Silver—The bullion supplies in the East are large, so we are informed, and there is no lack of silver. At the same time the price remains comparatively steady, while Indian advices as to rain are reported as encouraging for trade and for prices for silver bullion.

SILVER AND STERLING EXCHANGE

	June.	17	18	19	21	22	23
New York....	52½	52½	52½	52½	52½	52½	52½
London.....	24	24	24½	24½	24½	24½	24½
Sterling Ex....	4.8765	4.8790	4.8800	4.8805	4.8815	4.8810	4.8810

New York quotations, cents per ounce Troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Exports of silver from London to the East, as reported by Messrs. Pixley & Abell, year to June 10:

	1908.	1909.	Change.
India.....	£ 3,698,168	22,311,900	D. £1,866,258
China.....	616,400	1,075,100	I. 658,700
Straits.....	90,510	82,800	D. 7,710
Total.....	£ 4,305,068	£24,209,800	D. £ 835,268

Imports for the week, £205,500 from New York. Exports, £1500 to Egypt and £95,700 to India; £97,200 in all.

Copper, Tin, Lead and Zinc

	Copper.		Tin.	Lead.		Zinc.
June.	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per tin.	New York, Cts. per lb.	St. Louis, Cts. per lb.	St. Louis, Cts. per lb.
17	13½	13	58½	29½	4.27½	5.27½
18	13½	13	58½	29½	4.27½	5.27½
19	13½	13	58½	29½	4.27½	5.27½
20	13½	13	58½	29½	4.27½	5.27½
21	13½	13	58½	29½	4.27½	5.27½
22	13½	13	58½	29½	4.27½	5.27½
23	13½	13	58½	29½	4.27½	5.27½

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—The weakness on the Stock Exchange in the early part of the week June 17-23 had a pronounced influence on the temper of the holders of speculative copper both here and in Europe, and the market became deluged with offerings from these sources at lower prices. When the level for electrolytic had come down to the parity of the standard market, consumers showed more interest and a fair amount of business is reported as having been done in this country and abroad. There was no open market for Lake copper, sellers being disinclined to lower their prices in proportion to the decline in electrolytic, and for that reason such transactions as were reported appear to have been for special purposes.

The market has been very much mixed. The United Metals Selling Company has continued to ask 13½c. for Lake and 13¾c. for electrolytic, delivered, 30 days, but is doing no business at those figures, and is maintaining former asking prices simply because it has no present wish to meet the market. Calumet & Hecla is also understood to be temporarily out of the market. On the other hand the majority of the large selling agencies have been taking, at the declining prices, such business as has been offered, and certain first hands have manifested some pressure to sell. A good deal of speculative copper has been offered by second hands and some transactions have been made by them at prices below those which represent the bulk of the business, sales netting as low as 12¾c. having been made. The market for Lake has held up better than for electrolytic, because there is but little of this grade that is pressed for sale, and some consumers who have been obliged to buy have paid as high as 13¾c. for relatively small quantities. Sentiment as to the market in the immediate future is mixed. There remains some of the optimism of a little while ago, which is expressed in the idea that there will be a rally from present prices, especially if the London market takes a turn upward. In other quarters ideas are pessimistic in view of the continued large production. The market closes at 13¾c@13½c. nominally, for Lake, and 12¾c@13¼c. for electrolytic. The average of the week for casting copper has been 12¾c@13 cents.

Copper sheets are 17c. base for large lots. Full extras are charged, and higher prices for smaller quantities. Copper wire is 15c. base, carload lots at mill.

Some new prices on brass products were put in effect June 21. The base price on high brass sheets is now 14½c.; on high brass wire, 14¾c., and on high brass rods,

14¾c. per lb. The base price on brazed brass tubing remains 20¾c. per pound.

The London market on Thursday and Friday bordered on demoralization, spot at one time reaching £58 and three months, £58 15s. Supporting orders as well as bear covering stayed the decline. The close is higher and the tendency better at £58 12s. 6d. for spot and £59 10s. for three months.

For refined and manufactured sorts we quote: English tough, £62 10s.; best selected, £61 10s.@£62 10s.; strong sheets, £73 10s. @ £75 10s.

Exports of copper from New York and Philadelphia for the week were 7857 long tons. Our special correspondent gives the exports from Baltimore at 1215 tons copper.

Tin—In sympathy with copper, tin has shown a declining tendency in London. Shipments from the Straits are reported as being larger than anticipated, while consumption in the United States leaves much to be desired. The close is cabled at £133 for spot and £134 10s. for three months.

In the domestic market, consumers are holding off and cannot even be tempted by offers below the import basis, at which some dealers are trying to dispose of spot material. The market at the close is quoted at about 29½ cents.

Lead—Business has been quiet and prices are unchanged at 4.27½@4.32½ St. Louis, and 4.35, New York, for ordinary brands. Chemical lead has sold at St. Louis at 4.35 during the week.

The London market is neglected, the close again being a trifle lower at £13 for Spanish, and £13 2s. 6d. for English.

Spelter—The Senate on June 16 adopted the zinc ore schedule proposed by the Finance Committee, which provides for 1c. duty on the full zinc contents of all ores containing over 25 per cent. Lower duties are assessed on ore containing less than 25 per cent. which, however, means nothing to the smelters as they cannot treat ores for the purpose of making spelter containing less than 30 per cent. zinc, and besides the high freight charges make it impossible to import lower grades at a price which would permit of profitable mining.

The spelter market has shown persistent strength and while the extreme activity has subsided now that the worst is known, there is an inflow of orders and the close is firm and higher at 5.42½@5.47½c. New York, 5.27½@5.32½c. St. Louis.

New York quotations for spelter were 5.42½@5.47½c. for June 17 to 23, inclusive.

The London market is a shade lower in sympathy with the other metals there, the close being cabled at £21 17s. 6d. for good ordinaries, and £22 2s. 6d. for specials.

Base price of sheet zinc is 7c. per lb., f.o.b. La Salle-Peru, less 8 per cent. discount.

Other Metals

Antimony—The market continues dull with only small sales. Prices are nominally unchanged at 8½c. for Cookson's, 7½c. for U. S.; 7¾@7½c. for outside brands. Some sales are made subject to tariff should a tax be imposed.

Aluminum—No. 1 ingots are quoted 22 @24c. base; wire, 31@32c. base; sheets 33@34c. base. Business is rather quiet.

Quicksilver—There has been a slight improvement in business, but no change in prices. New York quotation is \$44.50 per flask of 75 lb. San Francisco, \$44 for domestic and \$42 for export. London price is £8 7s. 6d. per flask, but jobbers continue to offer at 5s. less.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, spot, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. The price for electrolytic is 5c. higher.

Cadmium—Current quotations 75c. per lb., in 100-lb. lots, at Cleveland, Ohio. In Germany, 450@475 marks per 100 kg. at factory.

Magnesium—Quotations for this metal are \$1.25 per lb. New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

British Metal Imports and Exports

Imports and exports of metals in Great Britain, five months ended May 31, figures in long tons, except quicksilver, which is in pounds:

Metals:	Imports.	Exports.	Excess.
Copper, long tons	54,128	27,984	Imp. 26,144
Copper, 1908....	64,936	27,400	Imp. 37,536
Tin, long tons....	15,846	17,193	Exp. 1,347
Tin, 1908....	18,624	17,368	Imp. 1,256
Lead, long tons....	91,615	19,430	Imp. 72,185
Lead, 1908....	99,198	23,488	Imp. 75,710
Spelter, i.g. tons.	45,279	2,715	Imp. 42,564
Spelter, 1908....	44,808	8,262	Imp. 36,546
Quicksilver, lb....	1,717,168	418,982	Imp. 1,298,186
Quicksilver, '08	2,129,327	754,965	Imp. 1,374,362

Ores:	Imports.	Exports.	Excess.
Tin ore and con.	9,686		Imp. 9,686
Tin ore, 1908....	10,827		Imp. 10,827
Pyrites....	328,597		Imp. 328,597
Pyrites, 1908....	366,162		Imp. 366,162

Copper totals include metallic contents of ore and matte. Exports include re-exports of foreign material. Of the imports in 1909 the United States furnished 128 tons copper matte, 14,203 tons fine copper and 15,086 tons lead. The lead was chiefly Mexican, refined in this country.

British Iron Trade—Exports and imports of iron and steel and of machinery in Great Britain, five months ended May 31, as valued by Board of Trade returns:

	Exports.	Imports.	Excess.
Iron and steel	£15,227,591	£ 3,090,849	Ex. £12,136,742
Machinery ...	11,595,901	2,000,790	Ex. 9,595,111
New ships....	2,799,954		Ex. 2,799,954

Total.....	£28,623,455	£ 5,091,639	Ex. £23,531,817
Total, 1908....	33,601,827	5,377,208	Ex. 28,224,619

Decrease in exports, £4,078,371, or 14.8 per cent.; decrease in imports, £285,519,

or 5.3 per cent. The quantities of iron and steel of all kinds were, in long tons:

	1908.	1909.	Change.
Exports.....	1,741,392	1,651,440	D. 89,952
Imports.....	420,887	460,792	I. 39,905

The increase in quantities imported was mainly in billets, blooms and other half-finished material.

Iron Ore Imports—Imports of iron ore into Great Britain for the five months ended May 31 were 2,402,147 long tons in 1908, and 2,345,119 in 1909; decrease, 57,028 tons. Of the imports this year 1,800,246 tons were from Spain.

Zinc and Lead Ore Markets

Joplin, Mo., June 19—The highest price paid for zinc was \$47 per ton, the base offerings for heads of sulphide ore ranging from \$43 to \$45 per ton of 60 per cent. zinc; slimes sold as low as a base of \$40; silicate prices ranged from \$16 to \$23; the average price, all grades, was \$40.68 per ton. The highest price paid for lead was \$60, medium grades commanding from \$57 @59.50. The average price, all grades, was \$58.04 per ton.

Only one bin of zinc ore was known to have sold on a base price of \$45; the bins of the producers in the north part of Webb City, who are holding for a \$45, base were passed by the purchasing agents.

SHIPMENTS, WEEK ENDED JUNE 19.

In addition to the above there was shipped to the American Zinc Ore Separator Company, 1,150,770 lb. and to the Joplin Separator Works, 66,000 lb. zinc concentrates.

Chemicals

New York, June 23—Business is improving a little both on spot and contract deliveries and dealers are looking forward rather hopefully to the fall trade. In a few lines, however, trade is backward.

Copper Sulphate—The market has been rather quiet and prices have been shaded a little. Current quotations are \$4.22½ per 100 lb. for carload orders and \$4.32½ @4.35 per 100 lb. for smaller parcels.

Nitrate of Soda—A good business continues to be done in this article at current prices which are unchanged at 4.15c. for spot and 4.12½c. for futures.

Arsenic—The market is rather quiet, with few sales, and prices quoted are 3¼ @3c. per lb. for white arsenic.

Mining Stocks

New York, June 23—The feature of the general stock market this week has been a marked reaction which carried down prices of a number of stocks. Steel Corporation issues receded, although the loss was not as marked as in some other stocks. Business was active and many shares changed hands.

On the Curb the copper stocks showed more or less weakness, with one or two exceptions. Nevada Consolidated was strong and reached its highest price at a little above \$24, notwithstanding the break in other shares. The dealings in this stock were large. Nevada gold stocks sold well and seem to be attracting more attention than they have been, which is rather unusual for a hot-weather week.

The Colaba stocks are gaining both in prices and in the volume of dealings.

Boston, June 22—There has been a gradual weakening in copper-mining share prices due to the lack of public interest. The market is almost entirely professional. The declines have been general and not confined to any particular class of stocks. No unfavorable mining developments are heard.

Amalgamated has broken almost \$7 during the week to \$77.75 with no recovery. The movement is entirely professional and is the result of the general decline in the New York.

One thing in favor of copper-mining shares is that they have had no prolonged upward movements, so that the decline cannot go very far. A buying movement in Nevada Consolidated for New York account caused a \$1.50 advance to \$24.12½. Shannon rights are off to 10c, but there has been a large business in them.

Gossip of the week tells of an amalgamation of the Boston Consolidated and the Utah Copper Company on a basis of 2½ shares of the former for one of the latter. Application has been made to list the new Arcadian Copper Company's stock on the Exchange as 76,000 shares of the old company have been exchanged for the new stock. In Mexico Consolidated affairs a former director is said to have sold some 15,000 shares in the market recently and put a part of the proceeds into Davis Day. The Alvarado silver mines are soon to be floated by an issue of 200,000 shares of treasury stock.
